Website: www.aafs.org

PROCEEDINGS

of the American Academy of Forensic Sciences 68th Annual Scientific Meeting

The Proceedings of the American Academy of Forensic Sciences is an official publication of the American Academy of Forensic Sciences (AAFS). It is devoted to the publication of the abstracts of technical oral papers and posters presented at the AAFS annual scientific meeting. These include various branches of the forensic sciences such as pathology, toxicology, anthropology, psychiatry, immunology, odontology, jurisprudence, criminalistics, questioned documents, digital evidence, and engineering. Similar submissions dealing with forensic oriented aspects of the social sciences are also included.

Please note that some of the abstracts included in the Proceedings deal with topics, results, and/or conclusions which are controversial. The publication of abstracts does not imply that the AAFS, its sections, or the individual section program chairs/committee members have verified or agree with the studies, results, and/or conclusions of each abstract. During the process of planning a scientific program, it is impossible to "peer-review" each abstract and presentation to the degree that is accomplished during manuscript review. Abstracts and presentations are accepted, in part, so that they can be critiqued and reviewed by other scientists. Thus, a forum is created to discuss controversial issues.

The views expressed in this publication are not those of the AAFS. The data and opinions appearing in the published material were prepared by and are the responsibility of the contributor(s), not of AAFS nor its respective employees, employers, officers, and agents. The AAFS does not supply copies of meeting papers. Please write directly to individual authors to obtain copies of specific papers. Presentation of some abstracts may have been scheduled or canceled after the publication of this document.

English is the official language of the AAFS and its meetings; neither oral nor written translations will be provided.

SPECIAL SESSIONS

S1 Innovative Science — How Advances in Technology Transform Forensic Science

Jeri D. Ropero-Miller, PhD, RTI International, 3040 Cornwallis Road, PO Box 12194, Bldg 7, Rm 211, Research Triangle Park, NC 27709; Marla E. Carroll, BS, Forensic Video & Audio Assoc, 6919 W Broward Boulevard, Ste 222, Plantation, FL 33317; Nancy Rodriguez, PhD*, National Institute of Justice, Dept of Justice/Office of Justice Programs, 810 Seventh Street, NW, Washington, DC 20531; Kenneth G. Furton, PhD*, Florida International University, International Forensic Research Institute, University Park, Miami, FL 33199; Jed S. Rakoff, JD*, US District Court, Southern District NY, 500 Pearl Street, New York, NY 10007-1312; John Collins, Jr., MA*, The Forensic Foundations Group, PO Box 227, Dewitt, MI 48820; Richard A. Guerrieri, MS*, 1 Corduroy Court, Stafford, VA 22554; Kurt B. Nolte, MD*, Office of Medical Investigator, MSC07 4040, 1 University of NM, Albuquerque, NM 87131-0001; Christina G. Hayes, BS*, St. Louis Metropolitan Police Department, 1915 Olive Street, St. Louis, MO 63103; Amanda R. Hale, MA*, North Carolina State University, 127 David Clark Labs, Campus Box 7617, Raleigh, NC 27695; and Zeno J. Geradts, PhD*, Netherlands Forensic Institute, Laan van Ypenburg 6, Den Haag, SH 2497 GB, NETHERLANDS*

After attending this presentation, attendees will better understand some best practices for technology adoption and implementation that have improved efficiency, quality, accuracy, reliability, and operational excellence in forensic sciences and beyond. Furthermore, the Interdisciplinary Symposium will help attendees understand the benefits and risks of emerging technologies to enable consideration and implementation.

This presentation will impact the forensic science community by highlighting how technology and its adoption can advance teaching and learning experiences, improve operational and legal standards, and embrace scientific innovation.

Whether at the scene of a death or a crime, in the forensic laboratory, or in the courtroom, technologies are used every day by practitioners to impart evidentiary proof and thereby solve cases. Forensic science has always been held to a high standard in order to uphold justice and for this to continue, forensic science must evolve and innovate.

As science progresses, answering a research question utilizing evidence-based science and technology typically leads to more questions. In fact, scientific knowledge begets new technologies, which beget new observations and scientific knowledge, which begets the next technological advancement. Keeping up with these advances in a forensic environment requires change, both operationally and culturally. Understanding, embracing, communicating, and when necessary, enforcing these changes requires the involvement of all stakeholders — the government, the criminal justice system, medical and forensic communities, and the public.

The 2016 American Academy of Forensic Sciences Interdisciplinary Symposium program will help forensic scientists keep pace with technology-enabled opportunities by highlighting advances in forensic science that have improved efficiency, quality, accuracy, reliability, and operational excellence. From forensic science disciplines including pattern comparison and forensic medicine to newer ones such as digital and multimedia sciences and next generation sequencing, innovation in science and technology is all about understanding what the technology brings to the science and how the science can harness new knowledge and information to improve impact and confidence.

This Interdisciplinary Symposium program will include prominent speakers who support technology adoption in academia, the government and private sectors, management, and the legal system. This program will continue with innovative and emerging technology "stars" among us and "integrators" of technology who will share how they have experienced and continue to transform their practice based on the latest technology.

Nancy Rodriguez, PhD

Keynote Presentation

As the federal government's lead agency for forensic science research and development, as well as the administration of programs to facilitate technical assistance, the National Institute of Justice (NIJ) has a prominent role in directing efforts to address the needs of the forensic science community. Using various sources such as the Report issued by the National Academy of Sciences (NAS) in 2009 — Strengthening Forensic Science in the United States: A Path Forward — NIJ has made an unprecedented investment to help strengthen forensic science in the United States. The NIJ remains committed to a strategy that couples rigorous research and development with technical assistance to serve the forensic science community. This approach provides the forensic science field with evidence-based research to create long-term success and ultimately improve public safety.

Kenneth G. Furton, PhD

Historically, higher education has been focused on disseminating knowledge and creating new knowledge, but increasingly, universities are becoming hubs for innovation and entrepreneurship and helping to drive the economic development

of the communities they serve. This trend can be transformative for forensic science as the translational research occurring in major academic forensic programs is spurring advances in many fields of forensic science that will impact the courtroom as well as the corporate boardroom. This presentation will highlight how academic forensic scientists have and will transform the field of forensic science in a variety of areas with a focus on detection science where trace detection of evidence and odors left from removed evidence is having a major impact on forensic science.

Jed S. Rakoff, JD

In the Anglo-American legal system, change tends to be incremental, with judges attempting to fit new situations and advances into the framework of previously developed legal principles; however, when it comes to technological advances, judges who rarely have much technological training or knowledge often find this difficult to do. This presentation will examine some of the difficulties judges have faced in dealing with technological advances in the forensic sciences and will suggest ways some of the problems of translating these advances into useable legal form might be better approached.

John M. Collins, Jr., MA

When forensic science professionals think of technology, their attention understandably gravitates toward innovations that relate directly to casework and the testing of evidence. But technology is not only about scientific practice. Managerial technology and innovations dealing with the administration of forensic science organizations are equally important. In this session, attendees will be introduced to the concept of administrative technologies and the way innovation can improve how forensic science organizations are managed. By examining some best-in-class practices from both inside and outside the forensic sciences, attendees will come to appreciate how technology can be leveraged in forensic science, not just for the testing of evidence, but in the management of people, customers, and organizational cultures.

Richard A. Guerrieri, MS

Forensic DNA analysis through Capillary Electrophoresis (CE) -based typing of Short Tandem Repeats (STR) is a well-established and successful technology with widespread technical acceptance. The emergence of Next Generation Sequencing (NGS) introduces opportunities for enhanced discrimination within mixtures and human remains, as well as identity, physical appearance, and ancestry relationships. NGS also introduces levels of change which are disruptive to present forensic laboratory approaches and will require modifications of established quality assurance practices and the development of new measures. NGS experiences in this area will be shared and implementation strategies for consideration by the forensic DNA community will also be discussed.

Kurt B. Nolte, MD

Advanced radiologic imaging modalities such as Computed Tomography (CT) scanners are transforming the practice of forensic pathology. CT allows for the rapid acquisition of a full volume of morphologic data that can be reconstructed in multiple planes as well as 3D perspectives. These images are detailed and can cover the full body. Research performed at the New Mexico Office of the Medical Investigator (OMI) has demonstrated that while both CT and autopsy have limitations in recognizing disease and injuries, they can be complementary in achieving the fullest diagnostic data set. This research has also demonstrated that in certain decedent cohorts, CT can supplant autopsy by developing an adequate diagnostic data set for accurately determining the cause of death. The OMI CT scanner is used daily by forensic pathologists to triage cases and to supplement and supplant autopsy.

Christina G. Hayes, BS

In the world of chemistry, there is a vast array of instrumentation that is available for use, yet in forensic drug chemistry, generally only a few instruments are utilized. By exploring the new technology available and comparing it to the standard instrumentation used with specific groups of drugs, it is possible to expand the drug chemists' repertoire for drug analysis.

Amanda R. Hale, MA

Digital imaging innovation is integral to advancing methods in forensic anthropology. The application of imaging techniques such as Computed Tomography (CT), 3D laser scanning, and digitization has already increased accuracy when performing putative identifications, ancestry estimation, and juvenile aging. In addition, digital imaging has increased database reference material used for both research and application. In combination with advanced statistical techniques, these provide a powerful new avenue for developing more precise methods in skeletal biology.

Zeno J. Gerdts, PhD

The development of digital and multimedia sciences is rapid due to the growth of data and the wide range of devices where digital evidence can be found; smartphones and most electronic devices now have digital storage that communicates with networks. Several sources state that 90% of the digital data has been produced during the last two years. Due to these rapid developments of big data, new techniques can be used and validation is crucial. Several developments in facial and image recognition based on deep learning algorithms have seen good progress and can be used in practice to assist forensic casework. New techniques on weak signal analysis will cause more possibilities for predictive methods. Also, if data is not accessible due to encryption, techniques for analyzing data streams can also help in cyber forensics cases.

S2 Viva La Forensics

Lara Frame-Newell, MA, Office of the Chief Medical Examiner, 400 E Jackson Street, Richmond, VA 23219; Sarah J. Ellis, MS*, North Carolina State Crime Laboratory, 121 E Tryon Road, Raleigh, NC 27603; Amanda R. Hale, MA*, North Carolina State University, 127 David Clark Labs, Campus Box 7617, Raleigh, NC 27695; Lindsay Saylors, 6258 W 60th Street, Chicago, IL 60638; Betzaida L. Maldonado, MSFS, 6215 Denmeade Drive, Atlanta, GA 30345; Jeremy M. Manheim, 2387 Shaker Lane, Apt F, Lebanon, IN 46052; Alicja K. Lanfear, PhD, Middle Tennessee State University, Dept of Biology, Box 60, Murfreesboro, TN 37132; Christina G. Hayes, BS*, St. Louis Metropolitan Police Department, 1915 Olive Street, St. Louis, MO 63103; Kelsey A. Carpenter, BS*, Unlisted, Howell, MI ; Brianna B. Bermudez, BS, 2297 Knob Hill Drive, Apt 14, Okemos, MI 48864; Jacob Griffin, BS, 16665 Danville Road, Danville, IA 52623; Ja'Neisha Hutley, MS*, 1500 Locust Street, Apt 1704, Philadelphia, PA 19102; John Nixon, CEng, MBA*, ARC, PO Box 66, Bippus, IN 46713; Raymond G. Miller, DDS*, 122 Covington Road, Buffalo, NY 14216; Gary M. Berman, DDS*, 9840 Haggerty Road, Belleville, MI 48111; John A. Williams, PhD*, Western Carolina University, Anthropology and Sociology, 101 McKee Hall, Cullowhee, NC 28723; Joseph Almog, PhD*, Hebrew University, Casali Inst of Applied Chem, Jerusalem 91904, ISRAEL; Joan A. Bytheway, PhD*, Sam Houston State University, College of Criminal Justice, Box 2296, Huntsville, TX 77341-2296; Helmut G. Brosz, BASc, PEng*, Brosz Forensic Services, 64 Bullock Drive, Markham, ON L3P 3P2, CANADA; Linton Mohammed, PhD*, Forensic Science Consultants, Inc, 433 Airport Boulevard, Ste 406, Burlingame, CA 94010-2014; Alan A. Price, MA*, University of Northern Colorado, Candelaria Hall, Rm 2285, Campus Box 147, Greeley, CO 80639; Nikolas P. Lemos, PhD*, OCME, Forensic Lab Division, Hall of Justice, N Terrace, 850 Bryant Street, San Francisco, CA 94103; J.C. Upshaw Downs, MD*, GBI ME, 925 A Mohawk Drive, Savannah, GA 31419; Claire E. Shepard, MS*, La Delta Community College, 7500 Millhaven Road, Monroe, LA 71203; Federica Collini, MD*, Via Mangiagalli 37, Milan 20133, ITALY; Noelle J. Umback, PhD*, OCME, Dept of Forensic Biology, 421 E 26 Street, New York, NY 10016; and Cheryl D. Hunter*, 403 Pioneer Creek Drive, Florissant, CO 80816*

After attending this presentation, attendees will have a better understanding of casework and solving cold cases within the fields of forensic science. Additionally, attendees will better understand how to create a resume and how to apply and interview for a job.

This presentation will impact the forensic science community by demonstrating cases where forensic science was key to case resolution. This will show attendees what real casework is and how real-life cases are solved. Cases will be presented from beginning to end.

Each year at the American Academy of Forensic Sciences (AAFS) Annual Scientific Meeting, the Young Forensic Scientists Forum (YFSF) provides a program for students and forensic scientists with less than five years of professional experience. The session allows attendees to interact with peers as well as with the professional speakers and to build professional relationships that foster growth and mentorship opportunities. Special session topics provide attendees with a broad overview of the many opportunities in the field of forensic science. In addition to the special session, the YFSF session offers two opportunities for young forensic scientists to present their own work or research: the YFSF Bring Your Own Posters (BYOP) Session and the YFSF Bring Your Own Slides (BYOS) Session. The Forensic Sciences Foundation (FSF) Emerging Forensic Scientists Award winner is also invited to present her award winning paper during this special session.

For the AAFS 68th Annual Scientific Meeting in Las Vegas, NV, the YFSF Special Session will present *Viva La Forensics!* The special session will be held on Tuesday, February 23, 2016, and will include speakers from many of the AAFS sections who will discuss cases where forensic science was key to solving the case. Through the presentations, attendees will learn how forensic science can be used to change the outcome of a case. Attendees will be exposed to the real life of a forensic scientist and to actual witness testimony.

Following the Tuesday session, the YFSF BYOP Session will be presented in the evening, giving young professionals the opportunity to showcase current cases and research being worked on in a poster format.

The annual YFSF BYOS Session takes place the evening of Wednesday, February 24, 2016, and will include presentations from students and young professionals. YFSF does not require presenters of YFSF BYOS and BYOP Sessions to be members of AAFS and does not require they attend the special session, but it is encouraged that they do so. The program will conclude on Thursday, February 25, 2016, with the annual YFSF Breakfast Session which includes a résumé review panel. Attendees of the breakfast session must be registered for the YFSF Special Session.

As is the tradition, the YFSF Breakfast Session focuses on developing professional skills for the next generation; however, this year will be a little different. Instead of planned speakers, members of various AAFS sections have been asked to participate in a Q&A Panel to help facilitate conversation between young professionals and professionals already established in their field. After the panel, attendees will have the opportunity to receive résumé assistance and feedback from AAFS members.

The special session provides students, young professionals, and AAFS members with a way to foster career-long relationships. The main goal of the YFSF is to encourage mentorship between young and veteran forensic scientists. Attendees are encouraged to apply for membership in the AAFS and are given guidance on the many opportunities available to aid in career enrichment.

*Presenting Author

BREAKFAST SESSIONS

BS1 Death in a Bathtub: The Defense of Drew Peterson

Jeffrey M. Jentzen, MD, University of Michigan, 300 N Ingalls, NI2D19 - SPC 5452, Ann Arbor, MI 48109; and Mary E.S. Case, MD*, 6059 N Hanley Road, St. Louis, MO 63134*

After attending this presentation, participants will better understand the courtroom procedures for admission of evidence and expert witness testimony. In addition, attendees will learn the factors involved in injury identification and analysis with an emphasis on the investigation of drowning.

This presentation will impact the forensic science community through the multidisciplinary reconstruction of one of the most riveting cases in recent American trial history. The presenters will detail the factors and evidence that influenced their decision process and assist future prosecutors, judges, and death investigators in the courtroom procedures.

In 2004, the body of Kathleen Savio, the third wife of policeman Drew Peterson, was found dead in the bathroom of her suburban Chicago home. Her body was found lying in an empty bathtub with a small laceration to the left back of the scalp. Froth oozed from her nostrils. There were some bruises to her left side. Toxicology analysis was negative for intoxicating drugs and alcohol. The initial investigation concluded that the death was the result of drowning and the coroner certified the death accidental. In 2007, Peterson's fourth wife, Stacey Peterson, disappeared — her body was never recovered. In light of Stacey Peterson's disappearance, authorities re-opened the investigation into Savio's death. Savio's body was disinterred in 2007 and re-examined in two separate autopsies performed by a group of forensic pathologists. The pathologist identified areas of hemorrhage over the left hip region, not appreciated at the initial examination. In light of the additional evidence, the experts concluded that Savio's death was a homicide.

In criminal cases, there is a constitutional dimension to hearsay. The Sixth Amendment gives criminal defendants the right to confront witnesses; since a hearsay statement is made out of court, there is no opportunity for the defendant's criminal defense attorney to cross-examine the witness, and thus no confrontation. This means hearsay statements are harder to get into evidence even via the traditional hearsay exceptions when they are used against a criminal defendant.

Prosecutors collecting evidence identified the fact that Stacey Peterson had confided with family and friends implicating her husband, Drew Peterson, as her murderer. Unable to question the dead witness, Stacey, prosecutors petitioned the Illinois legislature to create a new exemption to the hearsay rule, which became known as "Drew's Law." The law allowed for the admission of evidence in cases where the witness was not available to testify due to the actions of the defendant. Meanwhile, defense experts unsuccessfully attempted to exclude testimony related to Stacy Peterson's disappearance in a 2010 evidentiary trial.

The trial into the death of Kathleen Savio began in August of 2012. For more than six weeks of grueling testimony, the media provided the day-to-day revelations of the case. Five forensic pathologists testified in the case that called into question the cause and manner of death. All the pathologists agreed that Savio died of drowning. The pathology testimony rested on questions of the pathological findings of concussion, postmortem artifacts, orientation of injuries, and causes of accidental drowning.

In light of new legislation, the prosecution was allowed to present incriminating verbal testimony against Drew Peterson. Peterson was eventually convicted and sentenced to 38 years in prison for his role in death of Kathleen Savio. The jurors said that the most convincing testimony was the hearsay statements allowed into evidence under the new "Drew's Law." Prosecutors successfully fought to have statements made by Stacy Peterson and Savio to acquaintances admitted into evidence. In February 2013, the defense was denied a new trial. The trial left numerous questions unanswered and created a precedent of allowing indefensible hearsay testimony.

This presentation will provide courtroom presentation of evidence, expert testimony, the role of the medical witnesses, and criminalistic's evaluation in the trail of Drew Peterson. Participation of attendees is encouraged and will bring to life the tension of the courtroom in this precedent-setting prosecution.

Drew Peterson, Bathtub Drowning, Drew's Law

BS2 Death From a Distance: The Etiology of Serial Sniper Homicides

Robert J. Morton, MS, Fauquier County Sheriff's Office, 78 Lee Street, Warrenton, VA 20186; and Mary B. Collins-Morton, MS*, FBI Academy, NCAVC BAU4, Quantico, VA 22135*

After attending this presentation, attendees will better understand the unusual nature of serial sniper homicides and the difficulties faced by law enforcement, forensic specialists, and prosecutors in dealing with these cases.

This presentation will impact the forensic science community by highlighting the etiology of serial sniper homicides, the problems involved in determining case linkage between the different shootings, the circumstantial nature of the forensic evidence, and the difficulties involved in the prosecution of these infrequent crimes.

This presentation is designed to provide a historic overview of serial sniper homicides within the context of murder in general and serial murder, specifically. This presentation will also provide the statistical instances of serial sniper homicides compared to other types of murders as well as outline the investigative and forensic difficulties faced by law enforcement and the forensic community when dealing with one of these rare cases. Additionally, an extensive case study will be presented regarding a serial sniper case that took more than ten years to successfully convict the offender.

The Federal Bureau of Investigation's (FBI's) National Center for the Analysis of Violent Crime (NCAVC) is routinely consulted by federal, state, and local authorities in a variety of bizarre and repetitive violent crimes, especially homicides. NCAVC assistance was requested by local authorities regarding the case of a serial sniper. The four shooting incidents occurred during a highly contested divorce proceeding involving the offender. The first and second shootings were directed at the lawyer representing the offender's wife and the judge presiding over the divorce hearing, both of whom were shot at while inside their residences. Both were uninjured. The lawyer representing the offender's wife was shot at a second time while in his law office. The bullet struck him in the left eye, causing the loss of the eye; however, he survived the attack. The last attack occurred seven years later and targeted the male coworker with whom the offender's wife had previously had an affair. The victim, who was now a married father of three, was shot and killed in the yard of his residence. The laboratory determined the recovered bullet fragments from the shootings were consistent with a .22 caliber centerfire bullet and were fired through a similar rifle.

The investigation quickly focused on the offender; however, a series of search warrants failed to locate the specific rifle or similar ammunition involved in the attacks. The lack of evidence emboldened the offender and he began a public campaign professing his innocence and crusading against the "corrupt" criminal justice system. After one of the search warrants had been served, the offender placed a written response on the front porch of the judge who had signed the warrant, even though he lived in a different jurisdiction located more than an hour away. Additionally, the offender became active in the local political party and attempted to exert pressure on the local authorities to stifle the investigation.

Based upon the highly charged nature of this case, the "fear factor" generated by the shootings, the defiant demeanor displayed by the offender, and the lack of direct evidence, the police department requested assistance from the FBI. Both the local FBI office and the NCVAC provided assistance. During the joint consultation with the NCAVC, it was decided to convene a grand jury to address the four shootings. The strategy involved calling the offender as the first witness and outlining the legal ramifications for contacting and/or intimidating other witnesses testifying before the grand jury. The offender subsequently interfered with several witnesses, was charged and convicted of four counts of witness tampering, and was given a 21-year sentence. He was also indicted on numerous charges for the four sniper shootings, including murder and attempted murder.

The complex trial lasted more than two months. While there was no direct forensic evidence linking the offender, a variety of circumstantial evidence was presented outlining the unusual nature of the series of shootings, the relationship of the victims who were targeted, the offender's skill with weapons, and the various statements made by the offender. During the trial, numerous witnesses were called including forensic experts, investigators, the shooting victims, the offender's ex-wife, a member of the NCAVC, and a police department Special Weapons And Tactics (SWAT) sniper. The jury found the offender guilty of 31 separate counts and sentenced him to a life sentence plus 288 years.

This case highlights the complex nature of sniper murders, the value of circumstantial evidence, and the benefit of forensic experts, investigators, subject-matter experts, and prosecutors working cooperatively.

Serial Sniper, Serial Murder, Sniper

BS3 A Primer on the Structure and Activity of the National Institute of Standards and Technology's (NIST's) Organization of Scientific Area Committees (OSAC)

Barry K. Logan, PhD, NMS Labs/CFSRE, 3701 Welsh Road, Willow Grove, PA 19090; Mark D. Stolorow, MS, MBA*, NIST Special Programs Office, Organization of Scientific Area Committees, 100 Bureau Drive, MS 8102, Gaithersburg, MD 20899-8102; Sally S. Aiken, MD*, 5901 N Lidgerwood, Ste 24B, Spokane, WA 99208; Marc A. LeBeau, PhD*, FBI Laboratory, 2501 Investigation Parkway, Quantico, VA 22135; Gregory G. Davis, MD*, Jefferson County MEO, 1515 6th Avenue S, Rm 220, Birmingham, AL 35233-1601; and Christian G. Westring, PhD*, 2300 Stratford Avenue, Willow Grove, PA 19090*

After attending this presentation, participants will be able to discuss the structure and activities of the various committees and subcommittees that comply with the new NIST OSAC process established to develop standards and guidelines for the professional practice of forensic science.

This presentation will impact the forensic science community by introducing the OSAC process, its accomplishments, and its plans to the forensic science community, AAFS members, and meeting attendees. Information will be presented to assist attendees in becoming involved with and contributing to the process.

This presentation is designed to provide a brief introduction to the new and important structure created and driven by the forensic science community in partnership with NIST to develop standards and guidelines for professional practice of forensic science. If you have heard about this new organization and its assignment but want to better understand how it works, its potential to create systemic change in the forensic sciences, and opportunities for everyone to be involved; this is the session for you.

In 2013, NIST, in consultation with the Department of Justice (DOJ), began the process of seeking input from the forensic science community to create a registry of standards that represented the priorities and consensus of the practitioners of forensic science, but that was also subject to review, scrutiny, and input from other stakeholders including the criminal justice community (lawyers and judges), researchers, statisticians, and the general public. The intent was to create an open, transparent, and accountable process that would reduce the risk of bad science being used in the courtroom and create a means for more consistent practice and continuous improvement in the application of scientific methods and practice to criminal investigations.

In 2014, NIST created the OSAC to take on this task and began recruiting members. The organization is structured with a governing board, the Forensic Science Standards Board (FSSB), and served by three resource committees (Human Factors, Legal Resources, and Quality Infrastructure) and five scientific area committees (Biology/DNA, Chemistry/Instrumental Analysis, Crime Scene/Death Investigation, Digital/Multimedia, and Physics/Pattern Interpretation) to manage and support the work of the subcommittees, and the subcommittees themselves. The OSAC currently has 24 subcommittees (enumerated on NIST's web site) which either replaced or augmented the previous Scientific Working Group's (SWG's) standards development activities. The subcommittees and their derivative task groups work on the creation of new or adoption of existing United States or international standards, developed in a manner consistent with the widely recognized ANSI standards development process, subject to public comment, and publication in OSAC's approved standards and guidelines registries.

The process has been enthusiastically adopted by the forensic science community and, as of August 2015, standards were already in development for submission to the review and adoption procedure. In July 2015, the AAFS announced its intent to become an ANSI approved Standards Development Organization (SDO) and to take a leadership role in support of this new process.

Although there are many OSAC events which take place during the AAFS meeting, this presentation is designed to act as a primer to AAFS members and meeting attendees wanting to quickly get up to speed with the new process and the organization. The presentation will feature brief discussions from members of the various levels of the OSAC organization who will describe their roles and their progress to date and answer questions about how to become involved in this critical new process in support of the future and continued professionalization of forensic science.

OSAC, NIST, Forensic Science Standards

BS4 One Night in August: The I-35W Bridge Collapse in Minneapolis

Andrew M. Baker, MD, Hennepin County ME, 530 Chicago Avenue, Minneapolis, MN 55415; and Owen L. Middleton, MD, Hennepin County ME, 530 Chicago Avenue, Minneapolis, MN 55415*

After attending this presentation, attendees will understand the role of, the challenges posed to, and the lessons learned by the medical examiner in a high-profile, multi-fatality mass disaster.

This presentation will impact the forensic science community by providing deeper insights into the role of the medical examiner and forensic pathologist in managing a mass fatality incident. Special attention will be paid to techniques for identifying remains, communicating with families, informing the public, and working with other agencies and elected leaders.

On August 1, 2007, during the height of rush hour, the eight-lane I-35W Bridge in Minneapolis collapsed, sending scores of vehicles into the Mississippi River.

Bridge construction started in 1964 at a cost of ~ $5.2 million and the bridge opened in 1967. Originally striped for four lanes with an expected use of 66,000 vehicles per day, the bridge was restriped to eight lanes in 1988. At the time of the collapse, the 14-span, 1,907 feet long bridge carried an estimated 141,000 vehicles per day.

The medical examiner's office was one of some 75 city, county, state, federal, and private organizations that were eventually involved in the recovery of bodies and investigation of the collapse. Water visibility, current speed, biohazards, and steel and concrete in the river made the recoveries of the victims difficult. The medical examiner's office worked with law enforcement agencies and dive teams to develop a protocol for handling victims' remains with as much dignity and privacy as possible, given the challenges of the recoveries and the intense media scrutiny. Medical examiner investigators proactively contacted the families of the missing to obtain as much antemortem identifying material as possible to facilitate victim identification when bodies were found. In all but one case, identifications and autopsies were completed, and remains released to the families, in less than one day following recovery.

The challenges of the disaster site led to an operation spanning approximately three weeks before the last victim was found. This presentation focuses on the role of the medical examiner in the days and weeks following the bridge collapse, with an emphasis on identification techniques; communications with families, the media, and elected leaders; a review of what did (and did not) go well; and a summary of lessons learned.

Bridge, Collapse, Mass Fatality

BS5 Back to the Future — A Journey Across the Timelines and Possible Realities for the Future of Forensic Sciences

J.C. Upshaw Downs, MD, GBI ME, 925 A Mohawk Drive, Savannah, GA 31419; and Carla Miller Noziglia, MS*, 305 Ascot Drive, Aiken, SC 29803-7833*

After attending this presentation, attendees will have a better understanding of the history of the forensic sciences, including important dates and events. Additionally, attendees will learn how different sequences of events may have led to vastly alternate realities — allowing for an informed discussion about how to best guide the future course of forensic sciences.

This presentation will impact the forensic science community by discussing important past dates and events and detailing how these events helped shape the present state of the forensic sciences. This knowledge will allow attendees to positively steer the future course of forensic science practice toward the best possible outcome.

Thirty years ago, a film about a time-traveling teenager and mad scientist explored the concept of parallel realities based on skewing past, present, and future timelines dependent on actions in the "then" present. In one journey to our present day (October 21, 2015), a radically different yet oddly familiar and plausible future greets the two partners in time. Unfortunately, the law of unintended consequences has led to a projected future with disastrous results, necessitating intervention in the past. Attempts to change events then lead to further future problems, requiring actions in the past to "correct" the altered future and… the rest, as they say, is history.

The history of forensic science dates to antiquity but a few key dates and events include 1194 (Articles of Eyre re-establishing the office of Coroner in the United Kingdom); 1248 (The Washing Away of Wrongs — medical investigation of death); 1609 (document examination); 1784 (physical matching); 1840 (arsenic poisoning); and 1888 (Jack the Ripper). The modern forensic era extends through Galton's Fingerprints in 1892. Academic forensic science can be traced to 1902 at the University of Lausanne, Switzerland. Fingerprint evidence arrived in the United States by way of the 1904 World's Fair, courtesy of Scotland Yard. Chief August Vollmer, credited by many as "the father of modern law enforcement" soon after (1907) created the first crime laboratories as part of the Berkley, California Police Department, an idea which expanded with his move to Los Angeles in 1923. The Bureau of Investigation (later FBI) created the first national forensic lab in 1926. State crime labs began to be developed in the early 1930s. The same decade saw criminalistics established as an academic discipline. Other developments ensued with the eventual creation of the American Academy of Forensic Sciences in 1948 and the National Association of Medical Examiners in 1966. Advances continued with the passage of time, including the creation of the Federal Rules of Evidence (1975), DNA application to forensics (1980s), National DNA Database (1994), National Commission on the Future of DNA Evidence (1998), Paul Coverdell National Forensic Science Improvement Act (1999), National Academy of Forensic Sciences Report — Strengthening Forensic Science in the United States: A Path Forward (2009), and National Commission on Forensic Science (2013).

Utilizing the time vehicle to consider past actions and consequent future timelines, attendees will be led through several key points: past, present, and future - in the forensic timeline, in order to illustrate where then-current thoughts and/or actions skew the chain of events leading the community astray to an undesired future. Recognizing that certain future consequences can be traced to intersections of significant persons and actions at critical points in time leads to the conclusion that strategy may allow a directed and desired future result. The ultimate goal is to stimulate consideration of alternatives and discussion about the most prudent course for present-day actions to assure the best possible future.

"…[Y]our future hasn't been written yet. No one's has. Your future is whatever you make it. So make it a good one…."[1]

History, Forensic Science, Timeline

BS6 Thomas Krauss Memorial Bitemark Breakfast — Forensic Anthropology: Science Into Fiction

Kathleen J. Reichs, PhD, UNC - Charlotte, Dept of Anthropology, Charlotte, NC 28223; and Laura C. Fulginiti, PhD, Forensic Science Center, 701 W Jefferson, Phoenix, AZ 85007*

After attending this presentation, attendees will have a better understanding of the field of forensic anthropology and of the processes involved in creating fiction based on science. Emphasis will be on the writing of novels and screenplays.

This presentation will impact the forensic science community by providing an overview of the field of forensic anthropology and will describe techniques used in creating plausible fiction based on scientific procedures and principles.

Forensic anthropology is a sub-specialty within physical anthropology that combines knowledge of the human skeleton with skills in various areas of forensic protocol, including the recovery and analysis of modern human remains. A fully accredited forensic anthropologist will be certified by the American Board of Forensic Anthropology (ABFA). This requires achievement of a PhD, successful completion of a certification exam, adherence to a set of ethical standards, and regular reporting on continuing education requirements.

The forensic anthropologist analyzes compromised human remains — the decomposed, mummified, mutilated, burned, dismembered, and skeletal. She addresses questions of identity, manner of death, time since death, and, in some cases, postmortem body treatment.

The forensic anthropologist may function in any of a variety of contexts, including, but not limited to, medical examiner and coroner offices, government laboratories, disaster recovery teams, human rights efforts, law enforcement agencies, and the military. The forensic anthropologist does not operate in a vacuum but works with specialists in many other areas, including forensic odontology.

Over the past two decades, the analysis of crime scenes and crime victims has caught the attention of the general public. Forensic science has exploded onto the stage of pop culture, and practitioners have been portrayed in books and on the large and small screens. Dr. Temperance Brennan is the protagonist in 18 novels and the main character in the longest-running scripted drama in the history of the Fox network. Each of the Temperance Brennan books and the Young Adult (YA) Virals books and each episode of the television series Bones takes the reader or viewer into a context in which forensic investigators work. Each highlights a different area of expertise within the forensic sciences.

This presentation will discuss the process of fictionalizing forensic science by drawing upon the speaker's experience as a forensic anthropologist, a writer, and a television producer. The writing of a novel will be compared to the writing of a screenplay.

Anthropology, Novels, Screenplays

EVENING SESSION

ES1 The American Academy of Forensic Sciences (AAFS) Standards Development Process

Jennifer F. Limoges, MS, New York State Police, Forensic Investigation Center, 1220 Washington Avenue, Bldg 30, Albany, NY 12226-3000; Lucy A. Davis, BHS, LDH Consultants, 2944 N Mayo Trail, Pikeville, KY 41501; Mary C. McKiel, PhD*, The McKiel Group, LLC, 684 Southern Hills Drive, Arnold, MD 21012; Kenneth W. Aschheim, DDS, 44 E 67th Street, New York, NY 10065; Brad J. Wing, MS*, 4401 Chesapeake Street, NW, Washington, DC 20016-4423; and Teresa L. Ambrosius*, 410 North 21st Street, Colorado Springs, CO 80904*

After attending this presentation, attendees will understand the standards development process and how the AAFS Standards Development Organization (SDO) process will work.

This presentation will impact the forensic science community by educating attendees on how the AAFS will be involved in generating American National Standards for the forensic sciences.

The development of standards and guidelines for forensic science has become a priority within the criminal justice community. The National Commission of Forensic Sciences (NCFS) and the National Institute of Standards and Technology (NIST) Organization of Scientific Area Committees (OSAC) are actively pursuing this goal. Many AAFS members are leaders in the development of these documents. As one of the largest and most diverse forensic science organizations in the world, it is appropriate that AAFS share its members' expertise to ensure that standards are set by the forensic science community itself. AAFS has completed its application to the American National Standards Institute (ANSI) to become an accredited SDO. A wholly owned subsidiary corporation entitled the AAFS Standards Board, LLC has been developed to provide the mechanics of the Academy's SDO activities. As an accredited SDO, AAFS will be able to coordinate the approval of proposed standards to become American National Standards (ANS).

Numerous industries, government agencies, and consumers outside of forensic science rely on voluntary consensus standards to direct them in their processes. The National Technology Transfer and Advancement Act (NTTAA) of 1995 and the Office of Management and Budget Circular A119 requires federal agencies to adopt private sector standards, particularly those developed by SDOs, wherever possible in lieu of creating proprietary, non-consensus standards. While there are many accredited SDOs supplying forensic-specific standards, the overall process of standard development is not always clearly understood. All ANSI-accredited SDOs must follow the "ANSI Essential Requirements: Due Process Requirement for American National Standards." These requirements focus on ensuring the standards development follow a procedure that is open to all interested parties, is balanced to allow parties equal participation, no individual or group can dominate the procedure, and that due process including mandatory public review and comments is allowed. All comments received concerning a proposed standard must be addressed prior to final vote of the standard. The Essential Requirements also demand that final consensus must be achieved before a standard is allowed to go forth.

The AAFS SDO process will be run by the Academy Standards Board (ASB). The ASB will conduct their work in a manner that is open to public scrutiny and provide every stakeholder an opportunity to be heard, without dominance by any party, in compliance with national and international standard development procedures. The ASB will appoint a Consensus Body technical committee for each proposed standard. The Consensus Bodies will be comprised of volunteers from relevant and interested parties both within the Academy and the forensic science community as a whole. These Consensus Bodies will be responsible for creating and approving consensus standards to be submitted to ANSI via the ASB for approval as an American National Standard. The ASB will conduct this standards development in accordance with the requirements of ANSI's Essential Requirements for balance, lack of dominance, due process, and consensus. The Consensus Bodies will consider all public comments, views and objections to ballots, and resolve all negative comments prior to approving the proposed standard. The ASB process will be open and balanced and will encourage public comment.

This presentation will provide an overview of how the standards development process works and detail the specifics of the Academy Standard Board's process including a specific outline of each step in the ASB standard development procedures. Issues such as how balance is achieved within a Consensus Body, how interested parties are defined, and resolution of public comments will be discussed. Information will also be provided on how AAFS members and the forensic science community can participate in the ASB process and the Consensus Bodies. Time for questions and discussion will allow participants to fully understand the standard development process and the Academy's commitment to ensuring the quality of the standards development.

Standards Development, SDO, ANSI

LUNCHEON SESSIONS

L1 Working Stiff: Forensic Training & Public Relations in a Digital Age

Judy Melinek, MD, PathologyExpert Inc, 3739 Balboa Street, #102, San Francisco, CA 94121; T.J. Mitchell, BA*, PathologyExpert Inc., 3739 Balboa Street, #102, San Francisco, CA 94121; and Lindsey C. Thomas, MD, Hennepin County ME, 530 Chicago Avenue, S, Minneapolis, MN 55415*

After attending this presentation, attendees will understand: (1) how to write clearly and effectively about forensic science; and, (2) how to use public relations and social media to respond to breaking news.

This presentation will impact the forensic science community by helping forensic professionals understand how to effectively communicate difficult forensic cases to a lay public.

Just two months before the September 11th terrorist attacks, Dr. Judy Melinek began her training as a New York City forensic pathologist. With her husband, T.J., and their toddler, Daniel, holding down the home front, Dr. Melinek threw herself into the fascinating world of death investigation — performing autopsies, investigating death scenes, and counseling grieving relatives. Working Stiff chronicles Dr. Melinek's two years of training, taking readers behind the police tape of some of the most harrowing deaths in the "Big Apple," including a firsthand account of the events of September 11th, the subsequent anthrax bio-terrorism attack, and the disastrous crash of American Airlines Flight 587.

Lively, action-packed, and loaded with mordant wit, Working Stiff offers a firsthand account of daily life into one of America's most arduous professions and the unexpected challenges of shuttling between the domains of the living and the dead. The body never lies — and through the murders, accidents, and suicides that land on her table, Dr. Melinek lays bare the truth behind the glamorized depictions of autopsy work on shows like CSI and Law & Order to reveal the secret story of the real morgue.

Dr. Melinek will discuss how she and her writer husband collaboratively turned her daily journal about her forensic fellowship training at the New York City Office of the Chief Medical Examiner into a New York Times bestselling book. Writing clearly and effectively about forensic science draws candidates to professional training programs, increases the credibility and public profile of forensic scientists, and has the potential to increase both local and federal funding. Dr. Melinek will emphasize that in the digital age, where Twitter®, Facebook®, Instagram™, TV news, and bloggers set the tone and control the narrative around breaking cases, forensic scientists cannot continue to hide from the press behind an autopsy table or lab bench. Offices need to develop a public relations profile and utilize media relations to respond independently to press and public inquiries consistently — not just when there is a scandal or a high-profile case.

Forensic Pathology, Public Relations, Training

L2 Operation Lima Sea — Unidentified Remains of a Human Torso in Queensland, Australia: Case Report on the Collaborative Investigative and Novel Anthropological (Forensic) Responses in the Establishment of Identification

Donna M. MacGregor, MSc, Queensland University of Technology, Skeletal Biology and Forensic Anthropology Res Lab, School of Biomedical Sciences, Faculty of Health,, Brisbane, Queensland 4001, AUSTRALIA; Mikaela S. Reynolds, MSc, Level 5 Q Block,, 2 George Street, Gardens Point, Brisbane, Queensland 4001, AUSTRALIA; and Jon E. Birt, BA*, Queensland Police Service, Homicide Investigation Unit, Police Headquarters, 200 Roma Street, Brisbane 4073, AUSTRALIA*

After attending this presentation, attendees will better understand: (1) the extensive contemporary investigative processes involved in the establishment of identification employed by the Queensland Police Service; and, (2) how the integration of novel anthropological and forensic processes assisted the investigation process.

This presentation will impact the forensic science community by demonstrating the tenacity of investigators from the Homicide Investigation Unit, Queensland Police Service to pursue all potential fields of inquiry to establish victim identification or victimology.

In October 2013 at a regional center in Southeast Queensland, Australia, Queensland Fire and Rescue (QFRS) were called to a grass fire. Once extinguished, QFRS located the remains of a human torso. The head and hands had been severed, and the lower body from the mid lumbar region had also been removed. The head, hands, and lower body have never been located. Due to the limited nature of the remains, standard confirmatory identification techniques of fingerprints and dental records could not be utilized in this matter. DNA was collected; however, it did not match any national database. Familial DNA was investigated; this too presented no matches. Toxicology was also conducted for a full drug screening and a number of prescription medications were identified. Investigators conducted exhaustive searches of mobile phone tower activity, Medicare files, immigration files, and interstate missing person searches in an attempt to identify the remains.

The investigators then engaged the services of their police anthropologist to assist in the identification process. Using Multi-Slice Computed Tomography (MSCT) Digital Imaging and Communications in Medicine (DICOM) data (0.5/0.3mm) of the torso collected during the standard pre-postmortem scanning procedure at the Brisbane Mortuary, 3D virtual reconstructions of the bone surfaces, also called isosurfaces, were created. The virtual isosurface models were uploaded into a specialized 3D software program, Geomagic® Design™ X, where virtual measurements were conducted to determine sex and stature. The measurements were conducted using a new and novel protocol developed by the Skeletal Biology and Forensic Anthropology Research Laboratory (SBFAR) at the Queensland University of Technology, Brisbane.1 The virtual measurements were collected from various bones within the torso including the humerii, scapula, and clavicle. An attempt was made to determine age of the individual using the sternal end of the fourth rib; however, the CT resolution and small surface area presented difficulties in age determination other than determining the individual was an adult. Subsequently, discussions between the anthropologist and investigators resulted in an application to the State Coroner of Queensland that was supported to have the sternal rib end of the fourth rib excised from the torso, then macerated (i.e., soft tissue removed from the bone) using dermestid beetles. A final age range, sex, and stature were provided to investigators.

Ultimately in July 2014, the prescription medication information collected from the toxicology report matched with the anthropological information obtained from the CT data and rib maceration and assisted in the identification. The contributions of the "virtual" anthropological input into this matter were a first for Queensland. The utility of CT data proved extremely useful in providing a timely anthropological profile to the investigation team and in reducing the need to macerate the entire torso as would be warranted by traditional anthropological techniques to develop an anthropological profile. This matter also exemplifies the importance of collaboration between the various agencies and specialists involved in homicide investigations to achieve a successful outcome.

WORKSHOPS

W1 Information Does Exist Beyond the First Page of Your Google® Search! Tools and Strategies for Forensic Science Literature Searching and Use

John M. Butler, PhD, NIST, 100 Bureau Drive, MS 4701, Gaithersburg, MD 20899; Jeff Teitelbaum, MS*, 2203 Airport Way, S, Ste 250, Seattle, WA 98134; Susan Makar, MA*, NIST, 100 Bureau Drive, MS 2500, Gaithersburg, MD 20899; Amanda Malanowski, BS*, NIST, 100 Bureau Drive, MS 2500, Gaithersburg, MD 20899; Melissa K. Taylor, BA*, 100 Bureau Drive, Gaithersburg, MD 20899; and Matthew R. Wood, MS, Ocean County Sheriff's Dept, Forensic Science Laboratory, Toms River, NJ 08753*

After attending this presentation, attendees will understand the value of forensic science literature and how to search and use the literature to research topics of work-related interest, such as developing appropriate training materials and preparing for admissibility hearings.

This presentation will impact the forensic science community by serving as a venue for understanding the importance and value of forensic science literature and tools for finding information of interest to practitioners, researchers, and students.

Scientific fields are benefited by having access to and active use of published literature. Researchers publish their work to share knowledge with others and to gain recognition and prestige for their efforts. Knowing where to look in the scientific literature can help find answers to specific questions faced by forensic scientists. This workshop will present current practices and tools for discovering, using, and analyzing the literature from various forensic science disciplines. Strategies for reading, writing, and storing information on scientific publications will also be discussed.

As Jeff Teitelbaum notes: "Because there is no central repository for forensic science information, and because of the sheer number of disciplines under the forensic science umbrella, forensic scientists are often unable to locate material that is relevant to their needs."[1] The ability to use carefully selected keywords and keyword combinations to yield valuable information from publicly accessible search engines and databases such as Google®, PubMed®, Google® Scholar™, Google® Books™, WorldCat®, and the National Criminal Justice Reference Service will be demonstrated. Researchers having access to Web of Science™ or other commercial search tools and databases can extend their information searches.

Example searches will be conducted using both free resources available to any practitioner and specialized literature databases available to academic researchers and students. These case examples from multiple forensic disciplines will illustrate the challenges of searching the forensic science literature. Experienced reference librarians from the Washington State Patrol Crime Laboratory and the National Institute of Standards and Technology will demonstrate the types of searches that can be performed to provide information in addressing specific questions that may arise in training, troubleshooting, or testimony on the admissibility of a technique as well as to assess the impact of forensic science publications and collaborations. Approaches to visualize connections in the literature and to reflect the impact of specific authors or articles will also be discussed.

This workshop will include information on current journals by forensic discipline and a listing of literature-searching websites and other resources. The information being shared in this workshop is particularly timely given the January 2015 views document from the National Commission on Forensic Science regarding criteria for foundational, scientific literature supportive of forensic practice. Updates on ongoing activities involving analysis of forensic literature by the American Association for the Advancement of Science will be provided. Finally, a vision of potential future information resources to address current limitations of accessibility of forensic science literature will be shared.

Forensic Literature, Search Strategies, Information Resources

W2 Advanced Mass Spectrometry (MS) Techniques for Forensic Analysis: What Does the Future Hold?

Sherri L. Kacinko, PhD, 3701 Welsh Road, Willow Grove, PA 19090; Kenyon M. Evans-Nguyen, PhD*, 401 W Kennedy Boulevard, Tampa, FL 33606; David M. Schwope, PhD*, Aegis Sciences Corporation, 365 Great Circle Road, Nashville, TN 37228; Adam B. Hall, PhD*, Northeastern University, 360 Huntington Avenue, 140 The Fenway, 421TF, Boston, MA 02115; Jillian K. Yeakel, MS*, 3864 Courtney Street, Ste 150, Bethlehem, PA 18017; and Jason E. Schaff, PhD*, 2501 Investigation Parkway, Rm 4220, Quantico, VA 22135*

After attending this presentation, attendees will be better able to evaluate and select advanced MS techniques for solving various analytical problems in forensic science, including identification of unknowns, rapid throughput approaches to forensic sample preparation, novel ionization, and fragmentation approaches in hyphenated mass spectrometric techniques.

This presentation will impact the forensic science community by introducing attendees to some of the most recent advances in MS technology and their potential application to solve challenges in forensic investigations. This workshop has a strong interdisciplinary focus.

Advances in MS technology over the past decade profoundly affect the way forensic toxicologists and drug chemists approach screening of samples for the presence of controlled substances and other drugs. Immunoassay and Gas Chromatography/Mass Spectrometry (GC/MS) analysis, once considered the "gold standard" for initial detection and exclusion of specific drugs/drug classes, are being replaced by Liquid Chromatography/Mass Spectrometry (LC/MS) and Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS) methods due to increased availability of new instrumentation and performance improvements in existing technologies. An overview of the application of MS to drug screening in a modern toxicology laboratory, illustrated with casework data, will be provided. Topics will include the reasons behind the trend toward LC/MS analysis, comparison of the advantages of different MS technologies, different models for sample screening, and the use and limitations of high resolution and accurate mass data.

Multiplexing is a high-throughput solution which allows minimization of MS idle time by using two High-Performance Liquid Chromatography (HPLC) systems configured to one detector. This technique allows overlap of chromatographic runs while collecting spectrometric data in predefined windows. Two HPLC systems also permit simultaneous analysis by two methods employing different mobile phase systems. A 2D LC/MS/MS system increases sample throughput while preserving equilibration time.

Stable Isotope Ratio Mass Spectroscopy (IRMS) has been used in geochemistry and other fields for decades. Since the introduction of Gas Chromatography/Combustion IRMS (GC/C/IRMS), Compound-Specific Isotope Analysis (CSIA) has become increasingly utilized to determine isotopic composition in various fields. Several forensic applications of CSIA have been documented, including: determination of illicit drug preparations, identification of counterfeit pharmaceuticals, determination of doping in sports, and investigation of ignitable liquids and explosives; however, GC/C/IRMS is not without challenges. Labor-intense sample preparation, poor sensitivity, delicate instrumentation, and lack of uniform standards are difficulties which have hindered widespread adoption. This presentation will introduce attendees to GC/C/IRMS and detail current forensic GC/C/IRMS applications, with a focus on sports-doping steroid analysis. Present state-of-the-art and future possibilities of the methodology will be presented.

Several technologies for rapid and/or on-site MS have migrated from prototype instruments in research laboratories to fully validated commercial systems. Unreliability of color tests for preliminary identification of emerging synthetic drugs have increased interest in this instrumentation in forensic science. Additionally, fieldable MS has been used extensively in battlefield forensics for on-site identification of drugs and explosives. Currently, fieldable mass spectrometers can be used for preliminary identification and in the near future, these instruments could be used for rapid definitive identification in the field. Coupling simplified sampling strategies such as ambient ionization, solid phase microextraction, and thermal desorption have been key to success with these instruments. An overview of currently available instrumentation, primarily GC/MS and ion-traps, and their implementation by forensic scientists will be presented as well as a discussion of emerging instrumentation.

In the final presentation, attendees will be left with some thought-provoking ideas of where the discipline of forensic MS is headed in the future. From the days of Gas Chromatography/Flame Ionization Detector (GC/FID) use as a confirmatory approach to the current uses of LC/MS/MS and higher resolution options, the forensic science community has adapted to changes in the analytical technologies and implemented them to address challenges in casework. Technology will continue to advance and provide new opportunities for addressing challenges in our everyday work. This presentation will outline anticipated changes that will occur in the forensic drug and toxicology communities over the coming years.

Mass Spectrometry, Sample Preparation, Advanced Techniques

W3 How and Why You Can and Should Integrate Advanced Imaging Techniques Into Your Daily Autopsy Practice

Keith Pinckard, MD, PhD, Travis County Medical Examiner (Austin), 1213 Sabine Street, Austin, TX 78701; Evan Matshes, MD*, Academic Forensic Pathology Inc., 6927-48th Street, SE, Ste 200, Calgary, AB T2C5A4, CANADA; Sam W. Andrews, MD*, Travis County Medical Examiner's Office, 1213 Sabine Street, Austin, TX 78701; and Vivian Snyder, DO*, 572 Sheridan Square, Apt 3, Evanston, IL 60202*

After attending this presentation, attendees will: (1) understand the concept of "disciplinary cross-over" within medicine; (2) understand the "toolbox" approach to modern forensic pathology; (3) review the core science behind plain film radiography, Postmortem Computed Tomography (PMCT), and Postmortem Magnetic Resonance (PMMR); (4) understand practical applications of imaging techniques as they apply to natural and non-natural deaths; (5) understand the concept of "Targeted Tissue Assessments" (TTA) in the context of whole body PMCT and why TTA is not a partial autopsy; and, (6) review administrative considerations as they pertain to the installation and routine utilization of advanced imaging techniques.

This presentation will impact the forensic science community by exploring how forensic pathologists can and should take ownership of advanced imaging techniques in their daily practices.

The tools available to forensic pathologists have undergone few significant upgrades over the past few decades. While initially considered a luxury to many, plain film radiography has become standard technology in autopsy suites — so much so that National Association of Medical Examiners (NAME) accreditation of any system of death investigation requires access to a simple "X-ray" machine. Despite routinely ordering and interpreting radiographs, no forensic pathologist would describe himself/herself as a radiologist. Rather, like clinicians, they are making use of radiographs in their own practices — an example of "disciplinary cross-over" within medicine.

Although clinical medicine has quickly adopted more modern and advanced technologies, such as computed tomography and magnetic resonance imaging, forensic pathologists have been reticent to embrace such tools. Reasons for this include the high costs of installation and operation, training requirements for forensic pathologists and their support staff, and generalized "apprehension" about the adoption of new technologies. Some forensic pathologists resist the use of advanced radiologic techniques in their practices, citing concerns that "radiologists will take away their jobs." This concern ignores the reality that there is a paucity of radiologists interested in postmortem work, particularly in the context of the vast differential in remuneration between clinical radiology and forensic pathology. Furthermore, even if there were a plethora of radiologists interested in forensic imaging, none of them have the statutory authority or duty to investigate and certify death.

A handful of mortuaries have adopted Postmortem Computed Tomography (PMCT), and a very small number have adopted Postmortem Magnetic Resonance (PMMR) scanning. Some institutions make use of these technologies to augment their daily practices; others have taken a more focused "research-based" approach. This workshop takes a practical approach to the introduction and utilization of advanced radiologic techniques into daily forensic pathology practice. While extremely useful, PMCT is not an across-the-board replacement for autopsies; however, it is an excellent substitute for internal examination across broad categories of commonly investigated deaths. In general, PMCT can be regarded as either supplementing traditional examinations or supplanting them. Categories of death that traditionally undergo invasive autopsy, but that now can most often undergo only external examination with PMCT include: accidental blunt trauma, suspected trauma in the elderly and other at-risk adults, suicidal violence, some types of sudden natural death, and certain types of mechanical asphyxia, including choking on food.

Although rarely used, PMMR does have a solid and important function within the forensic pathology setting; the roles and limitations of this important, but very expensive technology will also be reviewed.

After this presentation, attendees should have grounded expectations for the important strengths and weaknesses of both PMCT and PMMR and should also understand fundamental administrative considerations regarding adoption, installation, and utilization of new technologies within systems of death investigation. Without any doubt, the introduction of advanced radiologic techniques into the autopsy suite represents the most important advancement in forensic pathology "tools" in the past century. This session will help to convince attendees that advanced imaging is within reach and can and should be utilized whenever possible within daily practice.

Postmortem Imaging, Autopsy, PMCT

W4 A Cloud Descends on the Courtroom: The Impact of Cloud Computing on Evidence in the Courtroom

Mark Pollitt, PhD, Digital Evidence Professional Services, Inc, 8509 Nicole Court, Ellicott City, MD 21043; Christopher J. Plourd, JD*, Superior Court, 939 Main Street, El Centro, CA 92243; Mary F. Horvath, MFS*, 6786 N Stuart Road, King George, VA 22485; Josiah Dykstra, PhD*, 1739 Carriage Lamp Court, Severn, MD 21144; Henry R. Reeve, JD*, Denver District Attorney's Office, 201 W Colfax Avenue, Ste 801, Denver, CO 80202; Abagail Abraham, JD*, AOL, 22000 AOL Way, Dulles, VA 20166; and Andrew Neal, MS*, TransPerfect Legal Solutions, 1717 Main Street, Ste 4450, Dallas, TX 75201*

After attending this presentation, attendees will better understand how the rapidly expanding technologies surrounding the storage and distribution of information and applications using what is commonly called "cloud computing" are impacting investigators, forensic examiners, and lawyers from the crime scene to the courtroom.

This presentation will impact the forensic science community by providing a brief tutorial on these technologies, giving attendees an appreciation of the difficulties in acquiring, analyzing, introducing, authenticating, and evaluating information stored "in the cloud." After attending this presentation, participants will be able to evaluate how these technologies are changing the practice of both law and forensic science.

The National Institute of Standards and Technology defines cloud computing as: "…a model for enabling ubiquitous, convenient, on-demand network access to a shared pool of configurable computing resources…"[1] Government and industry have rapidly adopted the use of massive computer resources to provide information storage and applications online for both internal and external use. While some of the uses of cloud computing are fairly obvious, such as web-based email, social media, and electronic commerce, the cloud technologies are increasingly being used for third-party applications and even in-house computing systems for handling evidence. One source suggests that by next year, more than one-third of all personal data in the world will be stored in the cloud.[2] This massive amount of data, coupled with the location of the computing resources distributed across the globe, presents a rapidly evolving set of problems for investigators, information security professionals, forensic scientists, and the legal community. Investigators and digital forensic examiners are already facing difficulties in locating, collecting, and utilizing cloud-based storage and applications. The courts are beginning to face challenges to admissibility and determining the reliability of proffered evidence.[3] For the entire forensic community, there are concerns regarding the privacy, confidentiality, and integrity of cloud-based data and applications.[4] Clearly, the impact of the movement of data and applications is beginning to have a major impact on the practice of forensic science.

This presentation will bring together computer scientists, forensic practitioners, information security practitioners, lawyers, and judges to discuss many of the emerging issues in this rapidly evolving field. Topics include: What is the Cloud, Legal and Practical Issues in Evidence Collection, Foundation and Admissibility of Cloud-Based Evidence, and Security and Privacy in the Cloud.

W5 UVIS Dental Identification Module (UDIM) — A Hands-On Workshop

Kenneth W. Aschheim, DDS, 44 E 67th Street, New York, NY 10065; Lawrence A. Dobrin, DMD*, New York City OCME, 471 E Westfield Avenue, Roselle Park, NJ 07204; Naeem Ullah, BS*, 421 E 26th Street, 10 Fl, Rm 1019, New York, NY 10016; Frank DePaolo, BS*, New York City OCME, 520 First Avenue, Rm 123, New York, NY 10016; John Fudenberg, MBA*, 1704 Pinto Lane, Las Vegas, NV 89106; Edward E. Herschaft, DDS*, UNLV School of Dental Medicine, 1001 Shadow Lane, MS 7412, Las Vegas, NV 89106-4124; John P. Demas, DDS*, 8814 Fort Hamilton Parkway, Brooklyn, NY 11209; and Davin Faulkner, DMD*, 290 Maddelena Avenue, Las Vegas, NV 89183*

After attending this presentation, attendees will: (1) become familiar with the functionality and features of the Unified Victim Identification System (UVIS), the UVIS Case Management System (UVIS-CMS), and the UDIM Stand Alone (UDIM-SA) software systems; and, (2) gain experience in order to enter, search, and compare antemortem and postmortem dental data utilizing the UDIM-SA software to identify a decedent.

This presentation will impact the forensic science community by providing attendees with a working knowledge of the UDIM, a component of a complete forensic case management system.

Following the World Trade Center and American Airlines Flight 587 disasters, the Office of Chief Medical Examiner of the City of New York (OCME) undertook a multi-year project of creating a browser-based fatality management system, UVIS, to aid in the identification of mass fatality victims. Based on research and lessons learned following these Multiple Fatality Incidents (MFIs), a new dental module, UDIM, was introduced to the forensic odontology community. The goal of this workshop is to provide hands-on experience with this module.

UVIS is a comprehensive disaster-management software system designed to coordinate all of the activities related to missing persons reporting and victim identification. By integrating key functions in Disaster Victim Identification (DVI), the software coordinates all the essential tasks necessary to develop an accurate manifest of potential victims as well as coordinating all components of remains management.

The UDIM can function as either an integrated module within UVIS or as a stand-alone dental identification software program, UDIM-SA. It is designed to be used for both daily operations or as an MFI dental identification module.

UDIM-SA is capable of recording detailed charting with its "click-to-code" interface, conduct complex searches utilizing optimized state-of-the-art unified ranking algorithms, and has the ability to find and highlight anomalies. The state-of-the-art coding interface not only allows the coding of restored surfaces, but also more complex restorations such as root canals, posts, implants, and implant abutments. Another unique feature of UDIM-SA is its detailed "self-correcting" coding interface. Built-in reference tables prevent the forensic odontologist from entering illogical or contradictory codes. UDIM also uses a unique color-coded comparison odontogram to decrease reconciliation times. This color coding allows for a more simplified comparison process of antemortem and postmortem data by highlighting explainable and unexplainable discrepancies. In addition, UDIM has extensive partial jaw fragment management, linking and joining of specimens, and unlimited image importation. UDIM-SA also has the ability to integrate with digital radiographic software which, with the unlimited image importation, makes UDIM a fully paperless dental forensic management system.

The current version of UDIM has been enhanced with a more robust security system. With four different odontology roles, administrators can control access to numerous submodules. From the forensic dental operator with read-only access to a full administrator, UDIM-SA allows a municipality to customize the software access based on the odontologist's skill and experience. The current version of UDIM has been upgraded to allow for the exportation of data and a customizable translation table allows conversion to other coding systems including the new Type-12 Dental Data set for the American National Standards Institute/ National Institute of Standards and Technology-Information Technology Laboratory (ANSI/NIST-ITL).

Participants will receive in-depth didactic instruction regarding the use of the program. This will be followed by hands-on training utilizing the UDIM-SA program to input both antemortem and postmortem dental information and perform reconciliation of this data utilizing UDIM advance comparison features.

UDIM, Dental Identification, Forensic Odontology

W6 Frequency Occurrence in Handwriting and Hand Printing Characteristics

Thomas W. Vastrick, BS, 522 S Hunt Club Boulevard, Ste 217, Apopka, FL 32703; Ellen M. Schuetzner, BA*, 6348 N Milwaukee Avenue, #161, Chicago, IL 60646-3728; and Mark E. Johnson, PhD*, UCF - Statistics Dept, University of Central Florida, Dept of Statistics, Orlando, FL 32816*

After attending this presentation, attendees will have a significant understanding and appreciation of the statistical bases for handwriting comparisons and how to present such information in court.

This presentation will impact the forensic science community by providing information that can be used in court cases in which statistical foundation and probability become weight or admissibility issues.

Handwriting comparison has a rich history in both documented methodologies and admissibility in courts across the United States. During a literature search, numerous small and moderate studies were found that collectively provided significant, but not necessarily proper, foundation for questions of uniqueness and probability of handwriting and hand printing characteristics. In 2009, the National Research Council Report, Strengthening Forensic Science in the United States: A Path Forward, sought to make recommendations to strengthen forensic disciplines through strengthening the statistical foundations for each discipline. In response to that report, workshop presenters Vastrick and Schuetzner designed and instituted a four-year comprehensive study of frequency occurrence in handwriting and hand printing characteristics within the United States. Vastrick and Schuetzner were joined by Mark Johnson and Michele Boulanger, both statisticians with experience in forensic science and standards of methodologies. Johnson and Boulanger were tasked with being the driving force behind the project and developing the procedural methodologies using Vastrick and Schuetzner as subject matter experts. The purpose was to make this a statistics project about handwriting comparison as opposed to a handwriting project with statistics. The project was funded by the National Institute of Justice (NIJ).

Based on Handwriting Identification: Facts and Fundamentals, along with current population statistics, Johnson and Boulanger produced a stratified sampling frame that best represented population sampling.[1] In addition, factors potentially influencing handwriting such as age, handedness, and education were taken into consideration in developing the frame. One aspect of this workshop will be to understand the population sampling selection process and attendees will have opportunities for some hands-on experience with this subject. Within the final report are the eventual results of the population sampling and these results will be highlighted to workshop attendees. It is hoped that this information will provide the basis from which future sample collections are made for handwriting collection purposes. In addition, this project provided quantitative results to the lists of factors that affect handwriting and these results will be discussed.

Each phase of the project had to undergo pilot testing and attendees will receive experience in each of the processes. The most influential pilot test was the Attribute Agreement Analysis (AAA). The statistical aspects of the AAA approach are embodied in the International Organization for Standardization Technical Report (ISO TR) 14468. Workshop attendees will conduct an experimental AAA.

Attendees will receive detailed instruction into the process of selecting and testing handwriting characteristics for this project. Originally, there were more than 2,500 characteristics selected, but pilot testing reduced this number significantly to 786. Attendees will learn about the initial selection process and the testing processes that were used.

Attendees will receive background information into the data entry process and will have the opportunity to use a database in order to understand the methods used in this research.

Product rule analysis was conducted on sets of specimens resulting in 97.01% of all cursive and 98.96% of all hand-printed feature pairs having a correlation of plus or minus 0.2 for which the product rule is satisfactory. Attendees will have the opportunity to use both the hand printing and cursive data spreadsheets to manually test the independence or interdependence of several pairs of characteristics.

Confidence limits are the range in which population samplings can be statistically accepted as being within 95% confidence level. This range will be explained and the mathematical equation used to establish 95% confidence limits will be applied several times in planned exercises in order to provide experience and understanding of this factor to the workshop attendees. The mathematical equation is moderately complex, so several exercises to establish a level of comfort will be required.

Each attendee will be provided a mock query and given several test samples from which they will have the opportunity to enter the data and receive a canned report as to the frequency occurrence of each character entered, their corresponding 95% confidence limits, and the results of applying the product rule to their results.

Each attendee will receive an electronic packet containing the final report of the research project, copies of historical papers concerning statistics in handwriting, copies of charts reflecting features that affect handwriting, publications concerning population statistics within the United States, a blank database, the final project spreadsheet of results, and a mock query. Also included will be several exercises as previously described.

Attendees will be cautioned about potential abuse and misuse of the project results and cautioned regarding the measures taken to limit the potential for abuse. Attendees will use the query in some of these ways to illustrate the potential for misuse.

The workshop will close with a roundtable discussion as to uses for this information and future enhancements to the

project. Attendees will be encouraged to solicit other forensic document examiners to receive training in the use of the material from this workshop. Due to its overall complexity, it would not be desirable to self-train.

Statistics, Frequency Occurrence, Handwriting

W7 Extreme Violence — Military vs. Civilian Crime Scene Investigation (CSI) Cases — Forensic Analysis and Disciplines in Practice

Brian L. Janysek, MFS, 2521 Hunter Mill Road, Oakton, VA 22124; Ryan P. Brokaw, MFS*, U.S. Army CID, Fort Benning CID Office, 7235 Gillespie Street, Bldg 108, Fort Benning, GA 31905; Scott Roeske, MFS*, 2635 Miner Road, Fort Sill, OK 73503; Jessica Ann Veltri, MS*, U.S. Army CID, 22nd Military Police Battalion (CID), Bldg 3148 2nd Division Drive, Joint Base Lewis-McChord, WA 98433; Donald Hayden, MFS*, 292 Harbour Lane, Richmond Hill, GA 31324; Steven Geniuk, MS*, 108 S Johnson Street, Bldg 31022, Fort Huachuca, AZ 85613; and Curtis E. Sparling, MA*, 10077A Horizon Street, Joint Base Lewis-McChord, WA 98433-9567*

After attending this presentation, attendees will understand multiple crime scene investigation methods, including injury pattern analysis, post-blast analysis, mass murder crime scene processing, and methods for solving an array of violent crimes.

This presentation will impact the forensic science community by identifying detailed and relevant aspects into the dynamics of multiple violent crime scenes observed around the world. The crimes were investigated by the Military Criminal Investigative Organizations. The investigations will present multimodal approaches elaborating on crime scene processing, evidence collection, interrogation methodology, post-blast reconstruction, medicolegal death determinations, and judicial hurdles and findings.

A group of military Forensic Science Officers (FSOs), each bringing decades of federal law enforcement experience within the United States Army Criminal Investigation Division, will present four high-profile investigations from the last ten years as well as discuss detailed steps every CSI responder experiences to process death scenes. There will be an in-depth focus on the significant challenges faced during the investigations, including special crime scene issues, language and cultural barriers, the combat environment, and examination of a stale murder scene. This presentation will explore the interaction of multiple forensic disciplines — crime scene examination, skeletal recovery, forensic anthropology, forensic odontology, DNA and computer forensics — as well as the utilization of young forensic scientists who used one case to springboard their careers.

In March 2012, a United States Army infantryman left his small outpost in southeastern Afghanistan, undetected and without authorization, and began a horrific killing spree. When finished, he invaded five homes in two villages, murdered 16 Afghani civilians (mostly women and children), and seriously wounded 6 others. The subsequent outrage from the Afghanistan nation would prevent Army investigators from reaching the crime scenes for more than three weeks. How DNA, firearms, and tool mark evidence helped link the subject to his victims and the scene of his crimes will be discussed.

A then-26-year-old female went missing in Missouri in 1985. The civilian investigation went cold until mid-2005 when information as to the identity of the murderer was received by the local sheriff's office. The investigation developed the probable location of the remains and ground/air searches, combined with additional interviews, identified a pond as a probable burial site. In 2006, forensic science and forensic anthropology college students, supervised by their professors, were engaged in the recovery. After federal and state coordination, an excavation was accomplished, which resulted in the recovery of skull fragments and a full mandible. Positive identification was made through dental comparison and DNA analysis and, in 2008, the suspect plead guilty to first-degree murder and sentenced to life in prison.

Military law enforcement aspects in processing crime scenes will be presented. Topics include: jurisdictional concerns at military bases inside and outside of the United States; cooperation with local law enforcement; working with a limited suspect pool; scene response while deployed and in austere environments; an overview of scene response and processing techniques; interviews; and, the military justice system.

The next case is a detailed account of a suicide bomber in Afghanistan who killed 11 and injured 22 in 2011. The topics discussed will include investigative operations in Afghanistan during the height of the 2011 Allied surge, post-blast analysis, methods of clearing and collecting evidence from the scene with live ordinance and biohazards, projectile trajectory, pattern injury analysis, and the search for additional suicide bombers.

The final case details how a self-employed Information Technology (IT) computer repairman found digital evidence on the cloud that his wife was having an extramarital affair while she was deployed. The couple's daughters made posters welcoming the mother home, but failed to show up at the welcome home ceremony. The day she returned from deployment, her husband printed the emails, leaving them on the printer, then killed his oldest daughter while she slept. When the other daughter awoke, he killed her before committing suicide. Elements of the crime scene, the physical evidence, and the significant digital evidence on the cloud, which was later recovered and corroborated the affair, will be discussed.

Investigation, Violence, Multidisciplinary

W8 From the Ashes — Transforming the Response to Mass Disasters

Anjali A. Ranadive, JD, SciLawForensics, Ltd, 1834 Overlook Ridge Road, Brookings, SD 57006; Edward Mazuchowski II, MD, PhD*, 115 Purple Heart Drive, Dover AFB, DE 19902; Robert E. Barsley, DDS, JD*, LSU School of Dentistry, Oral Health Resources, Rm 5345, 1100 Florida Avenue, New Orleans, LA 70119; Noelle J. Umback, PhD*, OCME, Dept of Forensic Biology, 421 E 26 Street, New York, NY 10016; Dean M. Gialamas, MS*, Los Angeles County Sheriff's Department, Technology & Support Division, 12440 E Imperial Highway, Ste 650, Norwalk, CA 90650; Joanna L. Collins, MFS, 20079 Stone Oak Parkway, Ste 1105-215, San Antonio, TX 78258; and Mary B. Collins-Morton, MS*, FBI Academy, NCAVC BAU4, Quantico, VA 22135*

After attending this presentation, attendees will understand how different agencies integrate various areas of forensic science in mass fatality incidents and how various forensic service providers can collaborate within and with these agencies to prepare for mass disaster events. In addition, attendees will better understand how emerging technologies are being leveraged.

This presentation will impact the forensic science community by highlighting what has been learned from numerous natural and unnatural disasters and how the forensic science community working together can prepare to respond to future incidents by teaching how to process and investigate mass disaster scenes and evidence.

A mass fatality incident occurs when the local resources that are normally used in response to a fatality event are overwhelmed or have the potential to be overwhelmed. This varies widely depending on the size of the departments and the type of incident. In order to effectively manage these incidents and conduct appropriate medicolegal death investigations, it is necessary to have an integrated approach between various forensic science disciplines.

This presentation will provide an overview of how various areas of forensic science are integrated in mass fatality incidents.

The goal is to introduce forensic scientists working their first mass fatality scene to scientific and administrative procedures generally used in processing the scene. In many incidents, it is not known at the onset whether the incident was accidental or criminal in nature, so the scene must be treated in the same detailed manner in all cases until conclusions can be made. A number of cases that have caused these agencies to improve their procedures will be discussed. There is more coordination between all state, local, and federal law enforcement agencies than ever before, addressing, for example, preparation, jurisdiction, responsibilities, and task assignments.

At the scene, it is necessary to identify evidence, decontaminate the remains as necessary, systematically document and recover the remains and personal effects, provide transport and/or temporary storage of the remains, and generate and maintain a chain of custody of all evidence, remains, and personal effects. This presentation will provide an overview of these procedures and how they may change based on circumstances.

Various resources available to law enforcement and medicolegal agencies developing their continuity of operations, contingency plans, and other plans will also be discussed.

At the intake area of the autopsy operations site, all remains are triaged, photographed by a forensic photographer, and given a unique identifier. Remains are scientifically identified by integrating the skills of fingerprint specialists, forensic odontologists, and DNA specialists. Radiographs are performed by radiology technicians and forensic radiologists interpret the images. Examination of the remains is conducted by forensic pathologists, toxicology samples are taken, and all evidence is collected and released to the investigative agency. Forensic anthropologists assist in the triage and provide expert consultation. The forensic pathologist usually completes the death certificate and certifies the identification and cause and manner of death. The remains and personal effects are released to mortuary affairs and communication is made with the families.

After intake, the triaged and numbered remains are viewed by the dental team. Forensic odontology provides a highly accurate, rapid method of identifying remains and associating partial remains. Successful dental identification requires trained forensic odontologists and support staff, a means of locating and obtaining the antemortem dental information, sufficient space and support to perform the postmortem examinations, and adequate Information Technology (IT) support and resources. The dental team works closely with the other forensic disciplines and with the members of the family assistance group, which gathers antemortem information. The dental team makes identification recommendations on the ultimate identity and release of the remains.

Once the examinations in the morgue are finished, the DNA laboratory begins work. Samples received may be much different than standard postmortem samples in source, amount, and condition, depending on the incident. DNA may be the only method to identify partial remains, but it is crucial to collect from all samples regardless of other identification modalities, since reunification of as many remains as possible is a major goal. Laboratories may find themselves inundated with samples almost immediately; this includes remains, known samples, and other family samples. Having the correct data in an organized fashion facilitates identifications; therefore, DNA-relevant information must be collected by the Victim Information Center. Tremendous improvements have been made in DNA database programs (capacity for Short Tandem Repeat (STR), Y-chromosomal Short Tandem Repeat (Y-STR), and mitochondrial DNA data as well as metadata), which can be used as a stand-alone system for mass disasters. Since 9/11, methods for bone processing and developing mini-STRs for degraded samples have advanced greatly.

Preparing for a future yet-unknown mass disaster can assist when disaster does strike. Developing a program for preparedness and training across agencies can be daunting but well worth the effort. This presentation will describe developing a

model program to coordinate Orange County forensic operations stakeholders with a first-hand look at the process development, planning, and implementation of a simulated mass disaster; this will assist in developing programs in the participants' own jurisdictions.

Mass Disaster, Coordinated Response, Forensic Scientists

W9 Strategies for Scientific Problem-Solving With Physical Evidence

Rebecca E. Bucht, PhD, Pietarinkatu 11 A 13, Helsinki 00140, FINLAND; Patrick Buzzini, PhD, Sam Houston State University, Chemistry/Forensic Science Bldg, 1003 Bowers Boulevard, Box 2525, Huntsville, TX 77314; Peter R. De Forest, DCrim, Forensic Consultants, PO Box 141, Ardsley, NY 10502; Douglas M. Lucas, DSc*, 5280 Lakeshore Road, #1111, Burlington, ON L7L 5R1, CANADA; Pierre A. J-L. Margot, PhD*, University of Lausanne, Ecole de Sciences Criminelles, Batochime, Lausanne 1015, SWITZERLAND; Alastair Ross*, Australia New Zealand Policing Advisory Agency, Level 6, Tower 3, World Trade Center, 637 Flinders Street, Melbourne 3005, AUSTRALIA; and Sheila Willis, PhD*, Forensic Science Ireland, Garda HQ, Phoenix Park, Dublin, IRELAND*

After attending this presentation, attendees will have better knowledge of and more insight into the development, underpinnings, and potential value of criminalistics from the perspective of experienced and knowledgeable forensic scientists.

This presentation will impact the forensic science community by addressing the often-overlooked but crucial question of which examinations to perform for a given case, how that decision-making is currently organized, and how it might be improved.

With the rapid growth of the forensic science industry, focus has been more on what scientific techniques to apply to questions of the law and how to increase the number of analyses done than on how those methods are applied. "Progress has been technical rather than fundamental, practical rather than theoretical, transient rather than permanent."[1] This quote in Paul Kirk's article, *The Ontogeny of Criminalistics,* still rings true.

Forensic science has developed on many fronts and there has been an increase in the demand for forensic science services, both in the number and size of forensic laboratories and in the number of university degree programs in forensic science. Efforts in the domain of laboratory accreditation, proficiency testing, and expert certification have contributed to ensuring the quality of the analytical work being performed. These, along with impressive technological advances, are obviously perceived as positive developments; however, there have also been more negative trends: forensic scientists are increasingly confined to the role of reactive technicians and rarely address the complete physical evidence investigation, especially in the context of complex and non-routine cases, and requests submitted to the forensic laboratory are often limited to factual, technical reports rather than the more complex and often more useful evaluative reports and reconstructions.

Responsibility for defining the scientific problem to be solved on the front end and of interpreting the significance of the scientific results within the context of the case on the back end lie primarily with non-scientist personnel. The research being conducted in the forensic science field also rarely addresses this front end and back end decision making. As a consequence, the contribution of forensic science rarely reaches its full potential.

The presenters bring with them a wealth of knowledge and experience concerning the evolution of forensic science industry in several countries. Along with a summary of how forensic science has evolved in their own jurisdictions, they will present their views on the key elements required for the optimization of the contribution of forensic science to criminal justice questions, particularly with regard to complex and non-routine cases, volume crime, and providing guidance to criminal justice policymakers.

Practical, interactive exercises will also be included to illustrate the key points made by the presentations.

Case Assessment, Forensic Intelligence, Complex Cases

W10 Practical Homicide Investigation®: An Evaluation of Homicides Involving Child Victims, Child Offenders, and Equivocal Death Investigations

Vernon J. Geberth, MS, MPS, Practical Homicide Investigation, PO Box 105, Marco Island, FL 34146; Barbara C. Wolf, MD*, District 5 MEO, 809 Pine Street, Leesburg, FL 34748; Thomas C. McAndrew, MA*, Pennsylvania State Police, 5933 Derick Drive, Orefield, PA 18069; and Andrea Zaferes, BA*, PO Box 601, Shokan, NY 12481*

After attending this presentation, attendees will better understand the unique aspects of child homicides and the dynamics involved in cases in which children are offenders. In addition, the presenters will discuss equivocal deaths and aquatic death investigations as well as the application of professional homicide investigation and medicolegal analysis to these events.

This presentation will impact the forensic science community by providing and familiarizing forensic scientists and investigators with the art and science involved in the professional investigation and medicolegal analysis in homicide investigations specifically as they relate to child homicides and equivocal death inquiries.

The investigation, medicolegal evaluation, and prosecution of child abuse-related fatalities are different from other types of homicides. The death scenes are often equivocal and open to different interpretations as to the cause and manner of death, sometimes due to manipulation of the scene by the offender. Likewise, the autopsy findings may be non-diagnostic and even absent, the so-called "negative autopsy." Such deaths may present as homicides, suicides, accidents, or natural deaths and may be altered by the offender to misdirect the investigation through staging of the scene and/or posing or mutilation of the body. They are open to interpretation pending further information of the facts, the victimology, and the circumstances of the event.

This workshop will focus on the investigative applications and best practice model of Practical Homicide Investigation® and the medicolegal evaluation of specific equivocal cases as well as the application of forensic pathology to the investigative process to accurately determine the cause and manner of death through a multidisciplinary medicolegal investigation as they relate to the investigation of equivocal deaths and offender-manipulated homicide scenes. The presentation will also feature cases that involve juveniles who commit murder with a level of sophistication and planning well beyond the age of the offender as well as aquatic death investigations involving children and adults.

Upon completion of this workshop, attendees will be familiar with the importance of crime scene integrity, the management of the homicide investigations, and the processing of the homicide crime scene as well as the application of the medicolegal investigation specifically as it relates to injury causation and the cause and manner of death.

Forensic Science, Equivocal Death, Aquatic Death

W11 Child Homicides: The Critical Role of Interdisciplinary Expert Collaboration

Evan Matshes, MD, Academic Forensic Pathology Inc, 6927-48th Street, SE, Ste 200, Calgary, AB T2C5A4, CANADA; Michael Cavilla, BA*, Calgary Police Service, Major Crimes Section, Calgary, AB, CANADA; Chris Milroy, MD, LLB*, Ottawa Hospital, 501 Smyth Road, Box 117, 4th Fl CCW, Ottawa, ON K1H 8L6, CANADA; and Jacqueline L. Parai, MD*, Ottawa Hospital, Division of Anatomical Pathology, 501 Smyth Road, Box 117, 4th Fl, Ottawa, ON K1H 8L6, CANADA*

After attending this presentation, attendees will better understand the main types of pathology seen in child abuse cases, the problems of identifying time sequences, how injuries are inflicted based upon the pathology present, and how law enforcement agencies can use medical and scientific evidence to investigate allegations of child homicide. Attendees will also learn how evidence is presented and challenged in homicide trials in the Canadian criminal justice system and how the Canadian legal system has dealt with undercover police operations and their admissibility as evidence.

This presentation will impact the forensic science community by providing information on different law enforcement techniques and how forensic medical evidence can be integrated into a complex investigation of a difficult and often contested area of the criminal justice system.

Sudden, unexpected, and/or violent death in childhood is uncommon to rare beyond infancy. Death investigators, forensic pathologists, law enforcement officers, and others faced with the investigation of such fatalities may be challenged by various factors including: (1) an incomplete, changing, or non-factual history of the circumstances of death; (2) complex pathology that cannot easily be interpreted within the vague historical data; and, (3) the reality that some injuries can be explained by non-criminal, unusual, bizarre, or rare activities of daily living that may initially seem implausible.

Well-documented public failures in pediatric forensic pathology have resulted in a shift in classic child death investigation. That is, while pathologists were often taught to "think dirty" when a child dies, modern wisdom has led to a shift toward "thinking truth." Without any doubt, all individuals involved in a child death investigation have a desire to reach factual, defensible conclusions and, within their roles, serve the public that pays for their services. Pediatricians, child protection services members, and law enforcement officers are, in general, advocates for "victims," and in that role, have distinct functions meant to protect other children and the public from real or potential harm. Forensic pathologists are in a somewhat unique role in that they are not advocates for any victim, person, family, or agency. Rather, they are advocates for science. It is this delicate relationship between "advocates" and the "non-advocate" forensic pathologist that will be explored in detail through case study, emphasizing the powerful partnership that can be developed through interdisciplinary collaboration, including, importantly, the use of so-called "hold-back evidence."

This presentation will review the modalities of death in the first decade of life (beyond infancy), with a focus on blunt trauma. Following this Socratic-style review, the presentation will shift to a single case study, the death of MJ, a 6-year-old girl who was found unresponsive at home with multiple injuries, and who later died in the hospital. The case study will revolve around the crucial and delicate relationship between a consulting forensic pathology expert and law enforcement officers, and will include a formal discussion concerning the oblique role for forensic pathology in a so-called "Mr. Big" undercover operation — a Canadian technique used in a number of different types of crime.

The independence of forensic pathologists, coroners, and medical examiners from the criminal justice system is a fundamental tenet of death investigation. When political and other influences are allowed to color medical opinions, a "truth seeking" paradigm cannot exist. That said, beyond the data sharing typical among agencies that investigate death, collaboration between an "expert" forensic pathologist and an investigative agency can promote and enhance the truth-seeking model and promote accuracy within the entire "system" of child death investigation.

Child Homicide, Expert Evidence, Undercover

W12 Development of a Reasonable Minimum Documentation Standard for Latent Prints

Heidi Eldridge, MS, RTI International, 3040 E Cornwallis Road, RTP, NC 27709; and Jeri D. Ropero-Miller, PhD*, RTI International, 3040 Cornwallis Road, PO Box 12194, Bldg 7, Rm 211, Research Triangle Park, NC 27709*

After attending this presentation, attendees will have: (1) hands-on experience in the difficulties of creating a one-size-fits-all policy for assigning documentation requirements to latent print evidence based upon the difficulty of the image; (2) experiential first-hand knowledge of some of the key attributes that factor into latent difficulty classifications; and, (3) a better understanding of the arguments for enhanced documentation as well as some practical suggestions on how to implement such a policy and the tools to design a policy that conforms to their own agency's operational needs.

This presentation will impact the forensic science community by furthering the dialogue surrounding the need for and implementation of realistic documentation policies while providing attendees with the practical tools and advice necessary to successfully craft and implement needed minimum documentation standards for latent print comparison work policies in their own laboratories.

Critics, courts, and researchers alike have been clamoring for increased documentation requirements for latent print comparison work. Accreditation standards support it and good scientific practice requires it, yet surprisingly few forensic laboratories even have a minimum documentation policy. Typically, the amount of documentation performed is either minimal in the extreme or is left entirely to the discretion of the individual examiner.

It seems that many laboratories incorrectly assume that taking the time to document will encompass a large volume of additional work without any measurable benefit, while it also seems to be that laboratories simply don't know how to accomplish designing and implementing such a policy. Part of the problem is that a sensible documentation policy should be predicated on the difficulty of the images in question — easy latents should require very little documentation, while more difficult latents should be subject to enhanced documentation. But as there are no generally accepted criteria for defining complex prints, it becomes difficult to determine when to apply these different policies.

This presentation will begin with a lecture on the philosophy of documentation — why do we document? Who are we doing it for? What makes it good scientific practice? Next will be exercises looking at actual latent prints and making quick, gut-reaction determinations about the quality of each image. Each image will be sorted into one of three categories based on perceived quality level and consensus among participants will be undertaken on these determinations.

Following the first exercise, the attributes of a latent image that make it more or less difficult will be discussed, and some visual training on what each attribute looks like will be reviewed in order to minimize variability between analysts in interpreting the criteria.

In a second exercise, participants will grade a set of latents according to the attributes that each displays. The results of this exercise will be reviewed as a group, once again determining what type of consistency can be reached among the participants.

Once the exercises are complete, the presentation will return to philosophy, with participants engaging in a roundtable discussion to identify useful features of a documentation policy and what are seen as the potential challenges to implementation.

Finally, suggestions will be offered for policies that could be implemented that will fulfill the goals of documentation, while having as small an impact on operations as possible.

The National Institute of Justice (NIJ) Forensic Technology Center of Excellence (FTCoE) is committed to improving the practice of forensic science and strengthening its impact to agencies dedicated to combating crime. This FTCoE workshop recognizes the importance of balancing the implementation of best practices with recognizing the operational needs of a functional forensic science laboratory.

Documentation, Latent Prints, SOPs

W14 Vaping: What You Didn't Know About Electronic Cigarettes — And Why You Should Care

Michelle R. Peace, PhD, VA Commonwealth University, 1015 Floyd Avenue, PO Box 843079, Richmond, VA 23284; Justin L. Poklis, BS*, Virginia Commonwealth University, Dept of Pharmacology & Toxicology, 410 N 12th Street, Rm 746, PO Box 980613, Richmond, VA 23219-0613; Richard N. Dalby, PhD*, University of Maryland, School of Pharmacy, 20 N Pine Street, PH N309E, Baltimore, MD 21201; Matthew R. Wood, MS*, Ocean County Sheriff's Dept, Forensic Science Laboratory, Toms River, NJ 08753; and Adam Polhemus, BA*, New Jersey State Police, PO Box 7068, West Trenton, NJ 08628*

After attending this presentation, attendees will be able to: (1) understand the mechanism and advantage of aerosols as a drug delivery system; (2) articulate the history of electronic cigarette development, their operation, and their components; (3) understand how electronic cigarettes are manipulated for abuse; and, (4) describe an analytical approach for e-cigarette components and e-liquid formulations to include real casework involving electronic cigarettes.

This presentation will impact the forensic science community by increasing awareness of electronic cigarette use as an emerging and popular drug of choice and the abuse trend leading to an international criminal justice concern. This presentation will also provide a foundation by which controlled substances units, forensic toxicologists, death investigators, and medical examiners can develop analytical methodologies and refine interpretative opinions when electronic cigarettes are used as a Route Of Administration (ROA).

Electronic cigarettes (e-cigarettes or e-cigs), known as "Personal Vaporizers" (PV) by avid users or Electronic Nicotine Delivery Systems (ENDS) by the industry, have experienced a significant increase in popularity for those seeking an alternative to smoking traditional tobacco products. These products are comprised of a battery-powered atomizer and a cartridge filled with a pharmaceutical (nicotine), flavorings, and water dissolved in glycerol products. E-cigarette devices are manufactured with a spectrum of personalization opportunities such as off-the-shelf non-customizable devices, customizations such as self-wrapping of the element, homemade wicks, self-preparation of the e-cigarette liquid formulation, cups to hold plant material, dripping vs. wicking, and wattage adjustors to administer a desired drug dosage.

The lack of enforced regulation has made e-cigarettes easy to access and has shepherded the nefarious use of electronic cigarettes. The use of the electronic cigarette as an illicit drug delivery device is touted on websites, forums, blogs, and videos describing how best to use them for specific illicit drugs such as tetrahydrocannabinol, methamphetamine, fentanyl, and heroin. They also explain at length the benefits of "vaping" illicit drugs as it can be done in public without question (there is no odor and vaping is not just acceptable, it is "cool").

Analyzing paraphernalia for drug usage is a practiced and conceivably straightforward methodology established in controlled substance laboratories nationwide; however, electronic cigarettes are still largely uncharacterized. Little is known or understood about their construction, let alone how they are potentially used to deliver illicit drugs. Additionally, from a toxicological perspective, little is documented regarding the delivery of nicotine, particularly as a function of power, for electronic cigarettes. Additionally, even less is known regarding the adulteration of electronic cigarettes and how the e-cigarettes are used or modified to optimize the delivery of an adulterant. Few peer-reviewed manuscripts exist in the literature that describe, define, and illustrate the use of electronic cigarettes.

This presentation will describe how electronic cigarettes work and their efficacy in drug delivery. Given that one of the roles of the forensic scientist is to define and characterize drug usage trends, this is being recognized as a relevant and identified threat to public health and criminal justice. This presentation will increase insight into the analytical efforts in controlled substances and in interpreting the findings and opinions of scientists, medical examiners, death investigators, and forensic toxicologists as related to electronic cigarettes. Attendees will also be more aware of the nature of drug usage, abuse, and overdose cases in which electronic cigarettes were used to deliver an illicit drug.

Research was supported by the National Institute of Justice, Office of Justice Programs, United States Department of Justice. The opinions, findings, and conclusions or recommendations expressed in this publication/program/exhibition are those of the author(s) and do not necessarily reflect those of the Department of Justice.

Electronic Cigarettes, Controlled Substances, Toxicology

W15 Addressing Damaged Mobile Devices for Data Acquisition

Steven B. Watson, BA, 4377 W 117th Court, Westminster, CO 80031; Samuel I. Brothers, BBA*, US Customs & Border Protection, 7501 Boston Boulevard, Rm 113, Springfield, VA 20598; and Richard Ayers, MS, 100 Bureau Drive, MS 8970, Gaithersburg, MD 20899-8970*

After attending this presentation, attendees will have: (1) explored the topic of damaged mobile devices; (2) reviewed the existing literature in this and peripheral research areas; (3) completed hands-on activities, including the examination of a ballistics-damaged mobile phone, the documentation of the damage to the device in a written report and with photo documentation, and the disassembly of a ballistics-damaged mobile phone; and, (4) employed a donor device via the "fraternal clone" method to repair the device for power on and data acquisition.[1] Attendees will affect the future direction of the damaged devices research by providing input into the damaged devices program.

This presentation will impact the forensic science community by establishing that simply because the device is damaged, this does not mean the data is gone. Successful data acquisition is possible from damaged mobile devices. While each of the damaged device focus areas has the potential for catastrophic damage to the intact electronic device, the potential of data residing on the embedded flash memory of these devices still exists and presents a new research area with limited scientific research in the field of digital forensics.

This presentation reviews a series of research projects that involved inflicting damage to mobile devices with scientific precision, then documenting the damage and remediation with the intention of publishing the results to the digital forensics community. The scope of the damaged devices projects includes liquid damage, thermal damage, impact damage, and ballistics damage.

Most agencies do not receive severely damaged mobile devices frequently enough to develop solid expertise in dealing with these devices. Early survey input suggests that most agencies receive a water-damaged device only once per annum. Introductory research has been completed related to blood-damaged mobile devices and draft compilation of best practices from the Scientific Working Group on Digital Evidence.[2,3] This presentation will review existing literature in the digital forensics community and other peripheral research areas, highlighting the integration of current results and findings from the initial projects into subsequent projects.

Severe damage to mobile devices potentially affecting the ability to extract data can be caused by a number of factors. Aqueous solutions cause damage through galvanic and electrolytic corrosion to the internal components of electronic devices, the hygroscopic tendencies of the printed circuit board materials causing myelination of the circuit board layers, and chemical damage introduced by the chemical properties of the aqueous solution. Thermal damage causes plastic components on the exterior and interior of the devices to melt or burn, burning of insulating layers, circuit boards, and batteries, and even melting of the solder connections that connect the circuitry of the mobile device. Impact damage from high-velocity impacts cause screens and cases to break or shatter, batteries to begin leaking, and components to be knocked off the circuit board. Ballistics damage from high-velocity projectiles or explosive materials causes catastrophic damage to areas of the device or, in some instances, complete disassembly of the device.

This damaged devices workshop seeks to ask the questions, explore the answers, and provide real-time guidance to the field on addressing damage mobile and embedded devices.

Cordner, MB*, Victorian Institute of Forensic Medicine, 57-83 Kavanagh Street, Southbank, Victoria 3006, AUSTRALIA*

After attending this presentation, participants will understand the structure of the new AAFS Center and current developments. Attendees will also be informed about key issues and applications within different global regions.

This presentation will impact the forensic science community by raising awareness of the new AAFS Center and important developments in global applications of humanitarian and human rights forensic science.

The value of the application of forensic science to humanitarian and human rights cases is growing as research expands, increasing the importance of the inclusion of such cases in education and practice. This presentation will provide current information on the development, structure, and progress of the new AAFS Center and its subcommittees, which will promote the application of contemporary forensic science to humanitarian and human rights cases around the world. In addition to providing access to AAFS resources to human rights cases, the Center will also offer support to AAFS members applying their skills to human rights projects, encouraging involvement in such instances. Perspectives from committee members will outline how the Center fits in with global advances and helps address issues relating to humanitarian and human rights forensic science.

Attendees will better understand the challenges faced and the benefits to be attained from further development and research in this area. Presenters from diverse research backgrounds will showcase how the new Center and its developments can fill a variety of niches in different contexts around the world. These perspectives emphasize the Center's potential for utilization in diverse situations and integration into scholarship. The Center will be comprised of an advisory committee, which will review proposals for support, and four subcommittees: Publications and Documents, Laboratory and Analysis Protocols (LAP), and Education, and Equipment. Additionally, many members have responded with their CV and personal letter of interest in participation as the Center advances. A database has been compiled of these individuals with the understanding that they may be contacted regarding circumstances related to their interests, specialties, and skills. This database and the committees are comprised of individuals from various regional backgrounds who represent all 11 sections of the AAFS.

The AAFS Humanitarian and Human Resource Center seeks to unify the resources of the AAFS to provide assistance for the growing demand of forensic science applications to human rights cases. It also seeks to encourage the integration of human rights issues into contemporary forensic science education as the field continues to expand.

Human Rights, Humanitarian, Resource Center

W17 Postmortem Monocular Indirect Ophthalmoscopy (PMIO)

Patrick E. Lantz, MD, WFU School of Medicine, Dept of Pathology, Medical Center Boulevard, Winston-Salem, NC 27157-1072; and Candace H. Schoppe, MD*, Southwestern Institute of Forensic Sciences, 2355 N Stemmons Freeway, Dallas, TX 75207*

After attending this presentation, attendees will be able to: (1) differentiate between direct and indirect ophthalmoscopy, noting advantages and limitations of each technique for the postmortem detection of fundal hemorrhages; (2) discuss the fundal location of retinal hemorrhages relative to their projected aerial image during monocular indirect ophthalmoscopy; and, (3) accurately draw retinal abnormalities observed during monocular indirect ophthalmoscopy with a simple ocular model on a fundal diagram.

This presentation will impact the forensic science community by providing an overview of PMIO, facilitating skill acquisition, and evaluating practical training and image acquisition with a smartphone.

Postmortem examination of the retina has relied on ocular evisceration. In most medical examiner/coroner jurisdictions, ocular enucleation is not a standard autopsy procedure unless child abuse is suspected, thus creating observational bias when citing the prevalence of postmortem fundal findings such as retinal hemorrhages (preretinal, flame-shaped or splinter, and dot/blot), perimacular retinal folds, retinoschisis, and postmortem artifactual retinal folds. PMIO permits examination of the decedent's posterior fundus and portions of the peripheral retina. The required equipment necessary for PMIO is relatively inexpensive and, when compared to direct ophthalmoscopy, the technique is less affected by corneal clouding, lens opacity, or vitreous hemorrhage and offers a wider field of view. PMIO uses a focal light source and an aspheric, convex condensing lens. An excellent source of coaxial illumination is a halogen or xenon surgical or procedural headlamp. This light source creates a collimated beam of light and permits the examiner to stabilize the condensing lens with both hands. Current aspheric lenses range from +14 to +40 diopters and are available in different diameters, permitting a field of view of 35°-55°. Postmortem corneal opacity may cause the fundus to appear hazy; however, by gently removing the epithelial layer of the cornea, the emergent image is usually of adequate quality to readily detect lesions such as fundal hemorrhages and retinal folds.

Learning how to perform and become proficient at PMIO can be perplexing and intimidating. Most pathology residents and forensic pathology fellows have limited exposure to indirect ophthalmoscopy. Because the projected aerial image is inverted and laterally reversed, precise descriptions or recording of fundal abnormalities can be challenging. Unlike binocular indirect ophthalmoscopy with a teaching mirror attachment, a procedural headlamp worn by the instructor does not permit the fellow or resident to view the projected aerial image simultaneously during PMIO. To address these learning obstacles it is necessary to develop tools and models to facilitate skill acquisition. Most smartphones can capture the image formed during indirect ophthalmoscopy using the smartphone's light source to illuminate the fundus. An hour or two with an inexpensive ocular model can shift the learning curve of the resident, fellow, or forensic pathologist substantially to the right in how to correctly position the light source and hold the indirect lens.

This presentation consists of an initial discussion and presentation that reviews the technique of PMIO, highlighting the optics, the equipment, and examples of abnormal fundal findings found at autopsy by PMIO and the use of a smartphone to capture the projected aerial image. Next, attendees will have a realistic learning experience by practical hands-on training with a procedural headlamp, an aspheric indirect lens, and a simple ocular model containing a variety of retinal abnormalities observed at autopsy. The ocular models have variably sized "pupillary" openings and some will have clear acetate over the openings to simulate corneal glare. Attendees will receive assistance in positioning the procedural headlamp, holding the indirect lens, viewing the projected aerial image, and accurately recording the retinal abnormalities. Attendees with smartphones can practice still image acquisition and video recording of fundal images produced by PMIO. Attendees will learn how to hold the smartphone with one hand while imaging the fundus and how to use a mini-tripod so the condensing lens can be stabilized with both hands, thus enhancing image stabilization and acquisition.

Following practice visualizing, diagramming, and image capture techniques of numerous fundal images, attendees have the option of being evaluated with a series of unknowns. Self-assessment of technical skill training and review of the unknown retinal findings concludes the presentation. As part of the presentation, attendees will be given a USB thumb drive with the introductory presentation, sample retinal images, fundal diagrams, and articles on PMIO.

Indirect Ophthalmoscopy, Retinal Hemorrhage, Smartphone

W18 Improving Your Image: How to Get the Best Out of Your Expensive X-Ray Equipment

Gerald J. Conlogue, MHS, Quinnipiac University, Diagnostic Imaging Program, 275 Mount Carmel Avenue, Hamden, CT 06518; and Mark D. Viner, MSc*, Cranfield Forensic Institute, Defence Academy of the UK, Inforce Foundation, Shrivenham SN6 8LA, UNITED KINGDOM*

After attending this presentation, attendees will: (1) have a better understanding of basic imaging principles using either film or a digital recording media; and, (2) incorporate these fundamentals into image optimization.

This presentation will impact the forensic science community by providing attendees with a better understanding of the association of basic radiographic principles, image acquisition, and optimization of image quality. The target audience for this presentation would include any individual involved in acquiring radiographs in a forensic setting. This would include, but is not limited to, medical examiners, forensic pathologists, dentists, anthropologists, autopsy technicians, and radiographers.

Medical imaging equipment and practices have advanced dramatically in the past two decades; however, due to the rapidly developing technology, many of the practices have not been adapted into forensics. The presentation delivery teams have had extensive experience in integrating technical advances with image optimization in a variety of settings including medical, anthropological, and forensics areas.

The Quinnipiac University Team has served as consultant to the Office of the Chief Medical Examiner for the State of Connecticut since 2002. During the academic semester, they not only radiographed victims but also trained the autopsy technicians on basic imaging fundamentals. Until the spring of 2014, all images were acquired using film, but since that date, the team has assisted in the transition to Computed Radiography (CR). In 2012, the team acquired valuable knowledge dealing with mass causalities from its experiences with the victims from the incident in Newtown, CT. In addition, the team has demonstrated alternative specimen imaging approaches utilizing industrial radiographic film, Multi-Detector Computed Tomography (MDCT), and tomosynthesis.

The Forensic Institute at Cranfield University/Inforce Foundation Team has extensive experience in delivering training in forensic radiography and mass fatality incidents. They deliver an annual Masters Level course for radiographers, anthropologists, and investigators and organize regular training and exercising for the United Kingdom Forensic Radiography Response Team. Team members have experience in routine Medical Examiner (ME) office work, cold case investigations, and many mass casualty incidents, including the 2007 London suicide bombings, Southeast Asia Tsunami, and investigations into genocide and human rights abuses in the former Yugoslavia, Sierra Leone, and Rwanda as well as in examination of archaeological remains. They provide advice on forensic imaging and emergency planning to the United Kingdom Government, United Nations International Criminal Court.

This presentation will begin with a general discussion of forensic imaging protocols that will include routine cases, cold case review, and mass casualty incidents in the United Kingdom and Connecticut. Although the use of film as an image receptor is declining, there are still locations where it is employed today. Several advantages of film will be discussed along with all the factors that must be considered with image optimization for this recording media, such as the formulation of a technique chart. In addition, the basic principles of film processing will be reviewed and will include consideration of automatic processing equipment and optimum operating conditions. An overview of the two types of digital image recording systems, direct Digital Radiograph (DR) and Computed Radiography (CR), will be reviewed. The advantages and disadvantages of each will be considered. Once the equipment basics have been discussed, the presentation will move on to methods and procedures to acquire images for routine and non-routine situations.

Forensic Radiography, Radiographic Film, Computed Radiography

W19 Diversity and Inclusion at the Forensic Science Workplace

Nikolas P. Lemos, PhD, OCME, Forensic Lab Division, Hall of Justice, N Terrace, 850 Bryant Street, San Francisco, CA 94103; Daniel S. Isenschmid, PhD*, NMS Labs, 3701 Welsh Road, Willow Grove, PA 19090; Chinyere M. Williams, BS*, 2527 8th Avenue, Apt 211, Oakland, CA 94606; and Cathy Tobin*, Cathy Tobin, PHR,525 First Avenue, W, Apt 210, Seattle, WA 98119*

After attending this presentation, attendees will be equipped with the necessary knowledge and tools to reflect on the past, put it into the context of the present, and create the conditions for an inclusive and diverse work environment.

This presentation will impact the forensic science community by helping attendees and their organizations better prepare to meet the evolving needs of a diverse and inclusion-focused workplace through the use of emerging trends, data, and practical application methodologies.

Diversity means understanding that each individual is unique and recognizing our individual differences. These can be along the dimensions of race, ethnicity, gender, sexual orientation, socio-economic status, age, physical abilities, religious beliefs, political beliefs, or other ideologies. It is the exploration of these differences in a safe, positive, and nurturing environment. It is about understanding each other and moving beyond simple tolerance to embracing and celebrating the rich dimensions of diversity contained within each individual. Inclusion puts the concept and practice of diversity into action by creating an environment of involvement, respect, and connection — where the richness of ideas, backgrounds, and perspectives are harnessed to create workplace, education, or business value.

All organizations need both diversity and inclusion to be successful. Companies with diverse workforces and leadership consistently outperform other companies and it is now more common than ever before for companies to routinely include in their workforce chief diversity officers.

The practice of diversity and inclusion reflects much of what is happening in the United States and the global workforce — it is in a state of constant evolution and flux.

Change is an expectation of the up-and-coming workforce. We, as forensic science educators, researchers, and practitioners, must drive and embrace this change and continue to create a more inclusive, healthier, and engaging forensic science workplace. The American Academy of Forensic Sciences has led the way and continues to encourage and support the membership's effort for a diverse and inclusive forensic workplace.

As workforces continue to become increasingly global, the need to understand and practice diversity and inclusion is ever more pressing.

This program will briefly review the historical perspectives of how societies and organizations have responded to, and were shaped by, human differences. Science has historically acted as an impetus for the political and social action needed to move diverse groups from segregation into mainstream society. The scientific community is often a conduit of change and it is that legacy that compels us to proactively raise awareness and create an inclusive and diverse environment that serves both our employees and the communities in which they live and work.

This presentation will provide tools that bolster diversity and inclusion in the forensic science workplace in order to improve our ability to raise awareness and create the conditions for an inclusive and diverse environment. This presentation will also demonstrate the existing connections between diversity, inclusion, and productivity and examine the nature of privilege in the workplace and how it negatively impacts employee engagement and organizational performance.

Attendees will be offered methods of identifying bias, whether positive, negative, seen or unseen, and will learn best practices for mitigating the all-too-often negative outcome of biases as well as preventing those outcomes by stopping bias at its source. Finally, the presentation will provide attendees with practical techniques in order for them to return to their workplaces and take action.

Diversity and Inclusion, Forensic Science, Workplace

W20 On the Leading Edge of Forensic Science

Zeno J. Geradts, PhD, Netherlands Forensic Institute, Laan van Ypenburg 6, Den Haag, SH 2497 GB, NETHERLANDS; Laura L. Liptai, PhD*, BioMedical Forensics HQ CA/FL, 1660 School Street, #103, Moraga, CA 94556; Robert M. Thompson, BS*, NIST, Special Programs Office-Forensic Sciences, 100 Bureau Drive, MS 8102, Gaithersburg, MD 20899; Katrin Franke, PhD*, Gjovik University, Teknologivegen 22, Gjovik, NORWAY; Arian C. van Asten, PhD*, Netherlands Forensic Institute, Laan van Ypenburg 6, The Hague, Zuid Holland 2497GB, NETHERLANDS; Gwyn Winfield, MA*, CBRNE World, 1 Winnall Valley Road, Ste 26, Falcon Communications, Winchester, Hampshire S023 0LD, UNITED KINGDOM; Victor W. Weedn, MD, JD*, George Washington University, 2100 Foxhall Road, NW, Somers Hall, Lower Level, L-12, Washington, DC 20007; Edward G. Bartick, PhD*, George Washington University, Dept of Forensic Sciences, 2100 Foxhall Road, NW, Washington, DC 20007; Mehdi Moini, PhD*, George Washington University, Dept of Forensic Sciences, 2100 Foxhall Road, NW, Washington, DC 20007; and Matthew T. Henshon, AB, JD*, Henshon Klein LLP, 120 Water Street, Boston, MA 02109*

After attending this presentation, attendees will better understand new developments in forensic science that may have impact on their work.

This presentation will impact the forensic science community by providing an overview of some of the new developments in forensic science and by opening a forum for the discussion of issues that arise regarding such developments. A wide variety of developments that will soon impact forensic science have been identified within the Think Tank Committee of the Forensic Sciences Foundation, Inc.

The development of drones and the forensic issues concerned with finding digital traces is seen as one of the topics. The use of drones in forensics is also one of the topics, especially as the methods have become much more attractive due to a drop in prices and increased availability.

The forensic discipline of firearm and tool mark identification currently relies on the optical micro-comparison of features that were produced by movement or by the impression of tool-bearing surfaces. The comparisons are conducted side-by-side with comparison microscopy, incorporating the skill and artistry of the examiner to balance the tool mark surface positions, angles, and illumination. If sufficient agreement is observed, a subjective determination of identity may be concluded. While proven to be accurate with a low false positive error rate, there has been renewed interest in objective comparison methods that are based on the actual 3D measurements of tool mark surfaces that are compared using statistical methods to objectively "measure" the similarity of the two surfaces. This presentation will review the most recent emerging technologies in surface topography measurements, their adaptation to firearm and tool mark analysis, and recent research in the objective measurement of similarity.

Another important topic is the investigation within a Chemical, Biological, Radiological, and Nuclear (CBRN) crime scene as the interrogation of CBR agents presents a variety of problems. Primary among those at the scene is an intense degree of political scrutiny and a high thermal burden. How do you accurately take high value samples when you are in a Level A "spacesuit"? How do you know where they are and what should you prioritize in the 20 minutes of air that you will have on the scene? The European Commission Generic Integrated Forensic Toolbox (GIFT) is answering these questions and can share some of the data.

The capabilities and usage of field instrumentation are growing rapidly. While these instruments do not have the versatility of laboratory instruments, they are being designed to carry out specific critical *in situ* field tasks that save time and money and reduce laboratory analyses. For example, hand-held Raman has been used for the detection of organic compounds such as controlled substances; however, since the detection is based on spectroscopic techniques, the results are preliminary and only good for screening purposes — findings still need to be analyzed by confirmatory laboratory techniques such as separation followed by mass spectrometry. To address this need, the George Washington University is developing a hand-held, ultra-fast capillary electrophoresis mass spectrometry for on-site, real-time analysis of chemical and biological compounds with optical isomer separation capability.

By allowing forensic analyses to be performed in real time at the crime scene or nearby facilities, valuable forensic information can be provided at the beginning of the investigation and can thus increase the quality of law enforcement. By introducing robust, easy-to-use portable forensic technology, the efficacy of the criminal justice system can be improved; however, such benefits can only partly be accomplished when the results are of an indicative nature and detailed analyses at a forensic laboratory remain necessary. The full potential of real-time forensic investigations can only be realized when the results can also be used as evidence in court. The Netherlands Forensic Institute (NFI) recently published a vision on integrated forensic platforms to merge the speed provided by real-time forensic analysis with the quality standards of accredited laboratory methods. Currently, the NFI is working on several such dedicated platform solutions that would enable DNA profiling, the chemical identification of illicit drugs, and the study of large amounts of digital evidence. This technological revolution could lead to a new role for forensic institutes in which forensic experts are focused on designing, developing, and maintaining forensic platforms, allowing other professionals in the criminal justice system to examine the physical, chemical, biological, and digital evidence. Forensic institutes could then focus their usually scarce expert capacity to interdisciplinary investigations in complex cases and forensic intelligence.

New Developments, Robotics, Automation

W21 Crime Assessment: Solving Crime Beyond Profiling

Richard D. Walter, MA, 1879 Chenango Street, Montrose, PA 18801; Klaus C. Neudecker, MD*, Schirmgasse 268, Landshut, Bavaria D-84028, GERMANY; Patrick Zirpoli*, 149 Spruce Swamp Road, Milanville, PA 18443; Amanda L. Farrell, PhD*, Marymount University, School of Education and Human Services, 2807 N Glebe Road, Arlington, VA 22207; and Lurena A. Huffman, BS*, Suffolk Police Department, 23 N Greenfield Avenue, Hampton, VA 23666*

After attending this presentation, attendees will understand that crime assessment is a method of crime investigation that utilizes key structures within the criminological continuum to examine the presence and/or absence of evidence found at the crime scene. Within this framework, there are four major classifications, referred to as the subtypes hereafter, which will be introduced and explained. These subtypes span the criminal spectrum and manifest in the expression of pathological constellations behaviors that can be recognized. Predicated upon these primary factors and coupled with additional principles, attendees will be able to grasp that understanding the crime scene through the crime continuum provides a critical understanding for the motives, methods, and opportunities of the crime.

This presentation will impact the forensic science community by providing attendees with the understanding that, although the human experience is variable, crime patterns can be coded to reveal interlocking and separate vectors. By doing so, recurrent elements and themes are developed to group common factors for various desires, intentions, and plans. Ergo, dependent upon the intended outcome, the crimes can reveal differentiated power and anger issues, levels of intimacy, and necessary idiosyncrasies that must be avoided. Accordingly, while acting out crime, the criminal many times inadvertently leaves these pre-crime, crime, and post-crime clues for investigators to find and analyze.

Historically, the work associated with profiling has utilized the psychological continuum to project clinical diagnosis and treatment to advise investigators on the *inference/meaning* of the evidence at the crime scene. Due to a lack of understanding of crime patterns, the traditional profiler may err by translating individual clinical data into the analysis of the crime patterns and meaning. By incorporating a *projective* psychological mythology into the crime continuum, the results will vary from minor errors to major contradictory flaws of evidence that may misdirect the investigation and/or judicial testimony.

In contrast to the risks associated with traditional profiling efforts, crime assessment measures the crime by known major subtype crime patterns (Power-Assertive type; Power-Reassurance type; Anger Retaliatory type; and Anger-Excitation type). These subtypes provide a structural foundation from which to analyze crimes, in effect becoming the DNA of crime. That is, the crime research has identified key elements of the crime which can shape the investigation and provide critical knowledge regarding the various elements of the crime, to include, but certainly not limited to, providing recommended methods of apprehension, interviewing strategies, and prosecutorial considerations. Most importantly, inasmuch as crime assessment is reflective in process, the investigators and experts can explain the process of the investigation without the perils of projection.

Note: This workshop will use many cases, videos, and discussion points to illustrate the conceptual and applied understanding of crime assessment. Given the nature of the material, it is not recommended for those persons who are sensitive and/or in some form of crisis.

Crime Assessment, Criminal Investigation, Offender Behavior

W22 Developing A Professional Code of Ethics in Digital Forensics

James R. Dibble, BS, 14606 N Gleneden Street, Spokane, WA 99208; Michael M. Losavio, JD*, Department of Criminal Justice, University of Louisville, Louisville, KY 40292; Keith W. Miller, PhD*, University of Missouri - St. Louis, 1 University Boulevard, 201 Education Admin Bldg, St. Louis, MO 63121; Marcus Rogers, PhD*, Purdue University, 401 N Grant Street, West Lafayette, IN 47907; Anthony Skjellum, PhD*, Auburn University, Dept of Computer Science and Software Eng, 345 W Magnolia, 3101 Shelby Center, Auburn, AL 36849-5347; Rhesa G. Gilliland, MS*, US Postal Inspection Service, Forensic Laboratory Services, 22433 Randolph Drive, Dulles, VA 20104-1000; and Kathryn C. Seigfried-Spellar, PhD*, Purdue University, Computer and Information Technology, 401 N Grant Street, West Lafayette, IN 47907*

After attending this presentation, attendees will be aware of issues that constitute a need to generate support for a unified professional code of ethics in digital forensics and will identify the steps necessary to establish such a code.

This presentation will impact the forensic science community by bringing together key stakeholders and representatives in the area of digital forensics, including academics, practitioners, and vendors to discuss the need for a professional code of ethics.

Almost every criminal and civil investigation now involves some form of digital evidence, yet we are a profession that lacks a clearly articulated, consensus-based code of ethics. In fact, it has been argued that without a code of ethics, the field of digital forensics cannot even *be* a "profession."[1]

Unlike some professions (e.g., legal, medical), digital forensics has neither a professional association on par with the American Bar Association (ABA) or the American Medical Association (AMA), nor a comprehensive code of ethics comparable to the ABA's *Model Rules of Professional Conduct* or the AMA's *Code of Medical Ethics*. Instead, multiple professional associations exist — some of which also provide certification for digital forensics professionals — such as the International Society of Forensic Computer Examiners (ISFCE), the International Association of Computer Investigation Specialists (IACIS), the Digital Forensics Association (DFA), and the American Society of Digital Forensics and e-Discovery (ASDFED), to name a few. A handful of these associations have established a set of professional ethical standards that members or certificate holders are expected to follow, but this is not the norm.

Sponsored by the National Science Foundation's Science, Technology, and Society (STS) program, a workshop was held in May 2015 to discuss the need for a professional code of ethics in digital forensics. Some of the core areas discussed at the workshop included: misrepresentation of digital evidence, misrepresentation of credentials, duty to verify/validate/test if the tools are operating as intended, duty to not exceed one's own knowledge, and a duty to uphold confidentially and privacy. In addition, there is a need to address conflicts of interest (e.g., confirmation bias, loyalty to employer, financial bias, hired guns). In fact, the Ethics Committee of the Council of Scientific Society Presidents (CSSP) reached out to members of the American Academy of Forensic Sciences (AAFS) in July 2015 to determine if there were examples of bias in terms of the acceptance of results based on source of funding. Although the CSSP is concerned with a specific conflict of interest, there exist similar concerns in the field of digital forensics with conflicts of interest, such as ethical dissent (e.g., acts of conscience, whistle-blowing) and professional neutrality (e.g., examinations are valid regardless of employer); however, unlike the CSSP, almost none of the existing codes have enforcement mechanisms in place to investigate allegations of unethical conduct by digital forensics professionals or sanctions for offenders if violations are uncovered.

Based on the recommendation of attendees at the Professional Ethics in Digital Forensics workshop, a larger workshop is sought at AAFS that will bring together key stakeholders and representatives in the area of digital forensics, including academics, practitioners, and vendors. The goals of the workshop are to raise awareness about these issues, to generate support for a unified professional code of ethics in digital forensics, and to identify the steps necessary to establish such a code.

Code of Ethics, Digital Forensics, Profession

W23 Considerations for Implementing Next Generation Sequencing (NGS) Technologies Into a Forensic Laboratory

Kimberly S. Andreaggi, MFS, ARP/AFDIL, 115 Purple Heart Drive, Dover AFB, DE 19902; Alice Briones, DO*, 599 Phillips Drive, Magnolia, DE 19962; Katherine B. Gettings, PhD*, NIST, 100 Bureau Drive, MS 8314, Gaithersburg, MD 20899; Erin M. Gorden, MFS*, Armed Forces DNA Identification Lab, 115 Purple Heart Drive, Dover AFB, DE 19902; Richard A. Guerrieri, MS*, 1 Corduroy Court, Stafford, VA 22554; Jennifer L. Higginbotham, MFS*, 115 Purple Heart Drive, Dover AFB, DE 19902; Christina M. Neal, MS*, Armed Forces DNA Identification Laboratory, 115 Purple Heart Drive, Dover, DE 19902; Walther Parson, PhD*, Muellerstraße 44, Innsbruck A-6020, AUSTRIA; Michelle A. Peck, MFS*, Armed Forces DNA Identification Laboratory, 115 Purple Heart Drive, Dover AFB, DE 19902; Joseph D. Ring, MS*, 115 Purple Heart Drive, Dover AFB, DE 19902; Peter M. Vallone, PhD*, 100 Bureau Drive, Gaithersburg, MD 20899-8311; Charla Marshall, PhD*, Armed Forces DNA Identification Laboratory, 115 Purple Heart Drive, Dover AFB, DE 19902; and Timothy P. McMahon, PhD*, Armed Forces DNA Identification Laboratory, 115 Purple Heart Drive, Dover Air Force Base, Dover, DE 19902*

After attending this presentation, attendees will understand NGS methodologies that can be applied to typical forensic specimens, as well as appreciate the considerations specific to the validation of NGS technologies.

This presentation will impact the forensic science community by discussing the benefits and challenges of implementing NGS into a forensic laboratory.

Over the past two decades, the gold standard for nucleic acid sequencing has been the chain-termination technique developed by Edward Sanger and colleagues in the late 1970s, now known as Sanger sequencing. In forensic laboratories, sequencing has historically been performed for mitochondrial DNA (mtDNA) typing, which is most applicable in cases with minimal quantities of nuclear DNA or in those lacking appropriate references for direct identification; however, there is strong forensic interest in the adoption of NGS technologies for wider use within the laboratory. NGS platforms enable massively parallel sequencing to generate millions of DNA sequence reads simultaneously. As such, NGS facilitates high-throughput DNA sequencing of multiplexed samples and DNA targets, which can be automated to streamline the laboratory workflow. Moreover, NGS data are quantitative and amenable to hands-off analysis within an expert system bioinformatic software package. This benefit thereby eliminates the need for visual assessment of electropherogram images that can slow the process of data review. The recent development of low-cost, high-throughput NGS platforms and commercial kits for forensic applications has made sequencing more accessible to forensic laboratories. Consequently, a demand has driven the forensic community to implement NGS technologies for routine use.

Forensic DNA laboratories around the world have begun the task of validating NGS technologies for missing persons and criminal casework as well as databasing efforts; however, these advances pose significant hurdles as traditional typing methods are traded for NGS assays, quantitation instruments, and sequencing platforms. First, NGS will require a transition from traditional length-based DNA typing methods to the sequencing of core forensic DNA markers. Consequently, sequence variation present in Short Tandem Repeats (STRs) will require an establishment of nomenclature for STR sequence analysis. NGS enhances the feasibility of entire mtDNA sequencing and enables Single Nucleotide Polymorphism (SNP) characterization as a feasible tool for genetic discrimination. In turn, the adoption of NGS sets the stage for ethical and legal discussions surrounding the use of phenotypic markers in forensics. Although other fields have adopted this technology successfully, forensic laboratories are beholden to strict guidelines and legal challenges that affect NGS implementation.

This presentation will provide a snapshot of the current progress of forensic DNA laboratories in the implementation of NGS technology. First, a historical perspective on DNA typing technologies will be presented to situate NGS within the context of methodological advancement. The presentation will follow with an overview of NGS methods available to the forensic community, and a discussion of laboratory infrastructure as it transitions to meet NGS requirements. Several presentations will focus on data generated from NGS workflows, including an evaluation of quantification systems as well as STR sequencing kits. The presentation will then turn to mitochondrial DNA sequencing, data analysis, and interpretation. Considerations surrounding the selection of NGS workflows and the challenges to the validation of NGS technology will be discussed. The final portion of this presentation will take the pulse of the broader forensic DNA community as it works to adopt NGS technologies in the laboratory.

DNA Analysis, Next Generation Sequencing, Validation

W24 Elder Abuse and Neglect: What's Happening to Grandma?

Amy Y. Carney, PhD, 210 Ivory Gull Way, San Marcos, CA 92078; Stewart D. Ryckman, MD*, 1468 Brookpark Drive, Mansfield, OH 44906; Debi Spencer, MFS*, CMR 467 Box 3364, APO, AE 09096; and Mark Carroll, BA*, Summit County Sheriff's Office, 53 University Avenue, Akron, OH 44308*

After attending this presentation, attendees will: (1) recognize the different forms of Elder Abuse (EA); (2) understand the motivation behind EA; (3) identify specific types of trauma found in EA; (4) recognize the injuries that may mimic trauma in the elderly; (5) understand the process of law enforcement response and death investigation in EA; and, (6) distinguish the similarities and differences between intentional neglect and self-neglect.

This presentation will impact the forensic science community by increasing the ability to detect the different forms of EA, distinguish abuse from neglect, and increase the awareness of the law enforcement response in cases of criminal abuse and death investigation.

The elderly, defined as those more than 65 years of age, are the fastest growing population in the United States, as well as in other countries around the world. By the year 2030, more than 20% of United States residents are expected to be age 65 and older, compared with 13% in the year 2010. By the year 2034, all of the baby boomers will be more than 70 years of age.

Elder abuse is a growing problem in the United States. Incidents of physical and sexual abuse, as well as neglect, continue to rise as the population ages. Maltreatment of the elderly is associated with increased morbidity and mortality, as well as increased health care costs. Fear, shame, and lack of knowledge contribute to underreporting of elder abuse and put the safety of elders at risk.

Definitions of elder abuse differ across the United States, as well as country to country, but usually include physical and financial abuse, verbal and emotional abuse, and neglect or potential neglect. Elder mistreatment can include both deliberate action or lack of action by a caregiver or family member and can occur in institutional or domestic settings.

It is this lack of agreement on the definition of elder abuse, as well as what constitutes elder abuse, that has made it difficult to assess incidence and prevalence. According to the World Health Organization (WHO), elder abuse is a single or repeated act, or lack of an appropriate action, that occurs in any relationship in which there is an expectation of trust and causes distress or harm to the older person. This definition excludes random acts of criminal behavior or violence, and it puts the trusting relationship at the center of the issue. It is this trusting relationship that often puts any resulting injuries into question, when physical signs of abuse are taken for the expected signs of aging, such as ulcers, bruising, or accidents, such as a fall. Injuries may be mistaken for result of disease or medication, and the possibility of abuse usually isn't considered.

In the 30 years since elder abuse was first identified as "granny battering," the medical and legal communities have come together to investigate elder abuse and add to the scientific knowledge in identification and intervention. Medical costs associated with violent injuries to elders in the United States are estimated at $5.3 billion dollars annually. This cost, as well as the morbidity and mortality associated with elder abuse, is expected to rise with the growth of the geriatric population.

The ability to identify abuse is the first step in assisting the elderly to safety. This presentation will assist attendees in recognizing the different types of elder abuse, understanding the motivation behind elder maltreatment, and provide specific case examples of abuse and neglect, which will assist the forensic professional in identifying and intervening in elder maltreatment. This presentation also provides tips and techniques for documentation, assists the forensic professional in distinguishing between accidental and criminal acts, and discusses the difficulties in prosecution in EA cases.

Elder Abuse, Neglect, Investigation

ANTHROPOLOGY

A1 Quantification of Radiologic Identification: Development of a Population Frequency Data Repository

Angi M. Christensen, PhD, FBI Laboratory, 2501 Investigation Parkway, Quantico, VA 22135; and Gary M. Hatch, MD*, University of New Mexico School of Medicine, Center for Forensic Imaging, MSC 07 4040, 1101 Camino de Salud, NE, Albuquerque, NM 87102*

After attending this presentation, attendees will be familiar with the development of a repository of population frequency data on radiologic features used in forensic identification comparisons.

This presentation will impact the forensic science community by allowing practitioners involved in radiologic comparisons to utilize population frequency data to enhance identification comparisons by providing statistical probabilities of correct and incorrect identification.

Radiographic comparison is a reliable means of personal identification in medicolegal death investigations. As with any identification approach (such as fingerprints, DNA, dentition, etc.), a key requirement of radiologic identification is that the trait or feature being compared in the antemortem and postmortem data must be relatively rare in the general population. The more unusual a shared feature is, the greater the probability that the identification is correct (i.e., that the two datasets originated from the same person). Population frequencies describe the frequency with which a feature is found in the general population, and they form the basis for the validity of any identification approach, including comparative radiology.

Most forensic radiology comparisons involve a relatively subjective assessment of the degree of similarity between antemortem and postmortem radiologic images (whether X-ray, Computed Tomography (CT), Magnetic Resonance Imaging (MRI), or other imaging modality), typically involving a qualitative visual comparison with the conclusion regarding an identification (or exclusion) being based on the skill and experience of the practitioner. Such assessments have been shown to be reliable in the sense that practitioners can locate matches (or pairs of images from the same person) among moderately large data sets, and misidentifications (or mismatches) have been demonstrated to be rare, with the ability to identify correct matches generally varying as a function of practitioner experience. However, subjective comparisons are insufficient for quantitatively assessing the strength (or evidentiary value) of an association and cannot typically be used to determine the probability of a correct (or incorrect) identification.

Rather than concluding that antemortem and postmortem radiologic images appear similar or the same, the results of radiologic identification comparisons are ideally expressed as likelihood ratios, which describe the probability of sharing radiologic features given that the identification is correct, over the probability of sharing the features if the identification is incorrect. The implementation of quantitative methods bolsters conclusions by providing statistical support for the probability of a correct (or incorrect) identification; however, quantitative methods require the acquisition and use of population frequency data for radiographic traits used in identification comparisons. In order to assess the probability of correct identification, the frequency of the trait shared in the antemortem and postmortem data must be known or estimated. Such data are currently absent for many features or difficult to access for others, precluding the use of quantitative methods in forensic radiologic identification in most cases. For certain skeletal/radiologic features, population frequencies may be reported in the journals and texts of disparate fields, often in publications unrelated to radiologic identification, making it difficult for forensic practitioners to locate the necessary data. For other traits, their population frequencies or variations in configuration require additional study.

In an effort to resolve this problem of insufficient or inaccessible data, this study is currently working to build a repository of estimated population frequencies for commonly assessed radiologic traits. Beginning with a thorough literature review, the first phase of the project involves mining currently available publications and data (including peer-reviewed medical and anthropological research and popular medical atlases) for documented population frequencies. The next phase of the project will involve the selection and analysis of additional traits using a large dataset of postmortem CT scans available through the New Mexico Office of the Medical Investigator. The database will eventually be made available through a publicly accessible website. Practitioners will then be able to reference the database, using the estimated population frequencies in forensic comparison casework. Researchers and practitioners wishing to participate in the data collection phase are encouraged to submit references or research to this study for possible inclusion in the database.

Forensic Radiology, Forensic Anthropology, Identification

A2 Systematic Bias in Estimating Body Mass of Korean Samples With the Morphometric Method of Ruff et al. (2005)

Yangseung Jeong, PhD, 419A Atkinson Drive, 905, Honolulu, HI 96814; and Eun Jin Woo, PhD, Seoul National University, Dept of Anthropology, San 56-1, Silim-dong, Kwanak-gu, Seoul, SOUTH KOREA*

After attending this presentation, attendees will appreciate the magnitude and cause of systematic bias in applying Ruff et al.'s morphometric method for body mass estimation to Asian samples, particularly to Korean samples.[1] Attendees will therefore be aware of the necessity of applying an adjustment factor that compensates for the bias prior to using this method for Asian populations.

This presentation will impact the forensic science community by quantifying potential errors associated with application of Ruff *et al.'s* morphometric method to Asian samples, and this research provides a theoretical basis for the bias.[1]

The morphometric method by Ruff *et al.*, a widely used body mass estimation method, is based on the cylindrical model.[1] The cylindrical model states that given specific density, the weight of a cylinder can be calculated from its height and breadth. For the morphometric method to have global applicability, the body composition of people (i.e., density of a cylinder) must be constant across populations; however, body composition differs between populations, particularly between Asians and non-Asians. It has been reported that the body fat percentage (BF%) of Asians is higher than of non-Asians with the same Body Mass Index (BMI) by 3%-5% points. Despite this difference, validation tests for this method have rarely been performed. In this research, the degree of potential bias was quantified when this method was applied to one population in Asia, Korean skeletal remains.

The body mass of 59 complete Korean male skeletons was morphometrically reconstructed using Ruff *et al.,* on which a regression equation was generated with the femoral head diameter.[1] Then, this new equation was applied to 54 Korean War casualties, whose estimated body mass was compared to the reported body mass of the Korean conscripts during the Korean War.[2] Although the 54 casualties were not identical to the individuals used in Park *et al.,* no significant discrepancy in body mass was anticipated between them since these individuals shared a similar background (i.e., Korean male conscripts in their early 20s during the Korean War).[2]

The results of the one-sample *t*-test showed that the estimated body mass from the 54 individuals (61.3kg) was significantly higher than the reported body mass (56.8kg) by 4.5kg (t=7.383, p<0.001).

In the cylindrical model, the weights of two cylinders with the same volume (i.e., same height and breadth) but different density cannot be identical. Due to a relatively higher percentage of fat in Asian populations, Asian and non-Asian individuals of the same shape (i.e., same stature and body breadth) do not have the same weights. In this case, the non-Asians will be heavier than the Asians, because muscle is denser than fat. In addition, the morphometric method of Ruff *et al.* was mostly based on non-Asian samples with only one Asian population, Japanese, included.[1] Therefore, the morphometric method devised from the non-Asian samples tends to produce overestimated body mass for Asian individuals. In fact, when this method was applied to the referenced Japanese sample using the given stature and bi-iliac breadth data in Ruff *et al.*, the Japanese body mass was also overestimated by 6.2kg and 4.7kg for females and males, respectively.[3]

In applying the Ruff *et al.*'s morphometric method to Asian populations, it is recommended that one be aware of the potential magnitude of bias associated with the method through a validity test and, if available, use an adjustment factor.[1]

Body Mass Estimation, Morphometric Method, Korean Skeletal Remains

A3 A Two-Pronged Approach to the Identification of Deceased Unidentified Border Crossers in North Carolina: 3D-ID and Geochemical Analysis

Chelsey A. Juarez, PhD, Department of Soc & Anthro NCSU, 1911 Bldg, 10 Current Drive, Campus Box 8107, Raleigh, NC 27695-8107; and Ann H. Ross, PhD*, North Carolina State University, Sociology & Anthropology, Campus Box 8107, Raleigh, NC 27695-8107*

After attending this presentation, attendees will better understand the utility of a two-pronged approach for the identification of deceased undocumented border crossers and, in particular, how this combination of tools is uniquely suited for unidentified persons from Central and South America.

This presentation will impact the forensic science community by providing results from a case representing a growing scenario in the Southeastern United States, the undocumented immigration of Central and South Americans. This presentation will add to research being implemented in forensic anthropology by demonstrating the increased precision for region-of-origin identification when 3D-ID software and geochemical analysis are combined. In addition, this presentation will also discuss the difficulties of dealing with the identification of "non-conventional" undocumented migrant groups (e.g., South Americans rather than Mexicans).

According to the Federal Bureau of Investigation's (FBI's) National Crime Information Center (NCIC) missing person and unidentified person files, as of December 31, 2014, there were approximately 40,000 to 50,000 unidentified dead in the United States. Human remains are thought to go unidentified for many reasons. According to Kimmerle et al., the missing who end up as unidentified are predominantly male, adult, foreign-born individuals, minorities, and at-risk individuals.[1] Undocumented status of many of the unidentified presents a unique challenge in the process of identification as conventional forensic identification tools such as family DNA-reference databases focus on United States citizens with next of kin. Thus, although the ability to solve a cold case is multifactorial, region-of-origin data is a critical component in successfully beginning the identification process.[2] Of the total foreign-born individuals, approximately 56% are from Mexico, 26% are from Central and South America, and as many as 26% of the total population of foreign-born persons are thought to be undocumented. Undocumented persons travel and reside throughout the country and, as a result, states such as North Carolina, Georgia, and Illinois are among the top states with the highest undocumented populations.[3]

The cold case described in this presentation represents one such case from the Wake County Sheriff's Office and Office of the Chief Medical Examiner's in Raleigh, NC. The unidentified remains of a single adult male initially found in 2003 were delivered to the NC State Forensic Anthropological Facility for analysis more than a decade after initial recovery. Biological sex and age estimates indicated the decedent was a male 41.9-53.7 years of age. Craniofacial morphology was characteristic of an individual of Hispanic ancestry. Metric and geometric morphometric ancestry assessment was conducted using both FORDISC® 3.0 and 3D-ID with similar, but critically contrasting, results. Metrically using FORDISC® 3.0, the individual classified as a Hispanic male with posterior (0.476) and typicality (0.655) probabilities. The software 3D-ID, which utilizes coordinate data, classified this individual as South American Male with posterior (0.4683) and typicality (0.4573) probabilities. In order to clarify region of origin, samples of tooth #30, a portion of the right femoral shaft, and a portion of the sternal end of right rib #12 were sampled for carbon, oxygen, and strontium isotopes. Results showed that tissue samples of all types were mechanistically indistinguishable within their categories and not consistent with a North Carolina acclimation, suggesting that the individual had been in North Carolina for less than five years (Bone 87Sr/86Sr ratio: 0.70802; Tooth 87Sr/86Sr ratio: 0.70813). Both samples had a standard error of +/-0.00001 (Femur δ18O value 22.7+/-0.341‰; Rib δ18O value 22.5+/-0.107‰; Enamel δ18O value 22.4+/-0.269‰). Oxygen isotopes in body tissues are obtained primarily from drinking water (~70%). The value of potential drinking water sources from body tissues was estimated to be -11.11‰. Utilizing the region-specific data from the 3D-ID combined with the isotope data, the region of origin for this individual was consistent with Southern Peru, which demonstrated a 87Sr/86Sr range of 0.70728 to 0.70906 and a drinking water range of -11.1 to -12.6.[3,4]

In conclusion, both isotopes and ancestry assessments are more successful at region-of-origin identification when combined. This case study suggests that in the case of undocumented Latinos, the combination of isotopes and 3D-ID may be better able to discern individuals of South and Central American descent and should be considered an important investigative component for forensic anthropologists working with these populations.

A4 Commingling Among Disinterred Remains of Unknown United States Service Members From the Korean War

Mary S. Megyesi, PhD, JPAC-CIL, 310 Worchester Avenue, Bldg 45, Joint Base Pearl Harbor-Hickam, HI 96853; Nicholas V. Passalacqua, PhD, 1559 Mount Vernon, East Lansing, MI 48823; Popi Chrysostomou, MSc, 6 Kallinou Street, Strovolos, Nicosia 2039, CYPRUS; and Michael R. Dolski, PhD, Defense POW/MIA Accounting Agency, 2211 Ala Wai Boulevard, #1015, Honolulu, HI 96815*

After attending this presentation, attendees will learn the nature and rate of commingling among purported United States service members, buried as unknowns from the Korean War.

This presentation will impact the forensic science community by demonstrating the extent of commingling in historic military cemetery contexts, identify the need for proper analyses with regard to establishing Minimum Numbers of Individuals (MNI), and discuss identification rates from disinterments under similar contexts.

The Defense POW/MIA Accounting Agency (DPAA) is a new Department of Defense (DoD) agency (established January 2015), formed by the merging of several pre-existing DoD organizations including the Joint POW/MIA Accounting Command (JPAC). This newly created agency is responsible for accounting for "persons whose remains have not been recovered from the conflict in which they were lost," specifically in regard to past United States military conflicts (National Defense Authorization Act (NDAA) 2015).

As part of the accounting effort, the DPAA routinely disinters United States service members buried as unknowns from cemetery contexts around the world. The goal of this project is to discuss rates of identification and commingling from disinterred Korean War United States service member caskets. This study examined all Korean War disinterments from the National Memorial Cemetery of the Pacific between 1999-2014. During this period, a total of 91 caskets were disinterred resulting in a total MNI of 108 individuals. In all Korean War disinterments, no commingling was *anticipated*, meaning that at least in theory, each unknown was buried as a single individual and any possible commingling was resolved by analysts prior to the internment of the unknown remains. From the 91 caskets, 16 (18%) were found to have commingling present and represent more than one individual; 1 of these represented an MNI of three, while the other 15 all represented an MNI of two individuals. Of the total 108 disinterred individuals (from the 91 caskets), 55 (51%) have been identified to date, and from the 33 individuals involved in commingled accessions, 10 individuals have been identified.

The vast majority of the commingled remains resulted from duplication of small skeletal elements (e.g., an extra pisiform or phalanx). When the small-element commingling is removed, the commingling rate drops to six caskets (7%), with a total MNI of 96, and the identification rate increases to 58%; however, the small-element commingling introduces a significant issue. The individuals represented by these isolated elements are (with current methods) unresolvable. Including these unresolvable cases in the total MNI results in a decrease of identification rate, while at the same time, we currently lack methods to identify these isolated elements, mainly due to the extremely poor DNA preservation. Accounting for these remains and accurately reflecting the number of individuals that are possible to identify in a commingled casket may become more of an issue as disinterments increase.

The JPAC developed a rigorous process using both historical and scientific assessments of case-related sources to develop lists of potentially associated candidates with each set of unknown remains prior to disinterment. The process was oriented to meet the past United States policy of disinterring only those unknown service members most likely to yield an identification. In April 2015, the DoD announced a new policy regarding the disinterment of unknown United States servicemember remains which lowered the standards required to disinter unknown servicemembers in order to increase the number of disinterments. Following previously established best-practice procedures, the identification success rate for identifiable remains is ~60% to date, with more identifications pending. The Korean War unknowns highlight how a rigorous multidisciplinary assessment of cases prior to disinterment *can* lead to successful and acceptable identification rates. A lowering of the standards to disinter greater numbers of unknowns will very likely have an adverse impact on identification rate, especially considering the current commingling rate present in Korean War unknown caskets. In addition, this policy will also affect WWII disinterments, which are known to have a dramatically higher commingling rate (~76% to date). Since the majority of interred unknowns are associated with WWII, the policy change may ultimately serve to raise disinterment rates, without a subsequent increase in identification rates. The commingling and related identification issues of the Korean War unknowns should inform our disinterment policies and practices, in contrast to escalating exhumations without considering these issues.

The views herein are those of the authors and do not necessarily represent those of the Department of Defense or the United States government.

Disinterment, Commingling, Identification

A5 Death Along the United States-Mexico Border: A Comparative View of Policy and Practice in Arizona and Texas

Kate Spradley, PhD, Texas State University, Dept of Anthropology, 601 University Drive, San Marcos, TX 78666; Robin C. Reineke, PhD, University of Arizona, 1009 E South Campus Drive, Tucson, AZ 85721; Mercedes Doretti, 578A Halsey Street, Ground Floor, Brooklyn, NY 11233; and Bruce E. Anderson, PhD, PCOME, Forensic Science Center, 2825 E District Street, Tucson, AZ 85714*

After attending this presentation, attendees will understand how the differences in medicolegal investigation strategies in two states along the border impact identification efforts of undocumented migrants that die attempting to cross the United States-Mexico border.

This presentation will impact the forensic science community by highlighting alternative strategies for the positive identification of missing and unidentified migrants that die along the United States-Mexico border.

Until recently, the majority of migrant deaths occurred in Arizona despite the fact that the Texas-Mexico border covers 1,254 miles of the 1,900 miles of the entire border; however, in 2012, Texas surpassed Arizona in deaths with the majority occurring in the Rio Grande Valley and more specifically in Brooks County, TX.[1] Unlike most Arizona border counties, most Texas counties with migrant deaths do not keep official statistics or provide systematic medicolegal death investigation for the undocumented migrants that die along the United States side of the border. Therefore, it is difficult to address how many migrants have died in Texas, where they die, and the final disposition of death.

The purpose of this presentation is to explore the differences in medicolegal death investigation efforts for undocumented migrants in Arizona and Texas and the proximate and ultimate factors that contribute to migrant identification. The focus will be on Brooks County, TX, and the Pima County Office of the Medical Examiner in Tucson, AZ, due to their high numbers of migrant fatalities. Comparisons are made between the types of medicolegal systems in each county, a medical examiner system in Pima County that serves three additional counties versus a Justice of the Peace in Brooks County. Each county is reviewed for its identification protocol including number of deaths, identification rate, means of identification, and ultimate disposition of unidentified human remains.

Results indicate that decedents along the border in Arizona are systematically taken to a medical examiner's office, examined by a forensic pathologist or anthropologist, and entered into the National Missing and Unidentified Persons System (NamUs). Identification methods include fingerprints, dental comparison, or DNA and, in some cases, circumstantial evidence. In contrast, Brooks County functions under a Justice of the Peace system. Prior to 2013, when a migrant died in Brooks County, TX, the body was often identified on the spot if Identification (ID) cards were found associated with remains or was most often taken to a funeral home that would attempt identification. If the funeral home was unsuccessful, the remains were buried in a cemetery with no systematic record keeping as to where the remains were buried. Although required by the Texas Criminal Code of Procedures, DNA samples were rarely obtained from the undocumented migrants for submission to the Combined DNA Index System (CODIS), which also requires a NamUs submission.

Between 2001 and 2013, Pima County, AZ, received 2,203 remains of individuals suspected to be undocumented migrants and 1,463 were positively identified, providing an identification rate of 66.4%.[2] In Brooks County, TX, it was published that 129 migrants died in 2013. It is unknown how many migrants were identified and the means of identification. While the final disposition of undocumented migrants is largely known for Brooks County, TX, it is unknown for the rest of the border counties in Texas.

The Pima County Medical Examiner's Office is located in close proximity to the border, employed a forensic anthropologist, and has the ability to use governmental or private laboratories for DNA identification, which contributes to a high identification rate. While three medical examiners exist in close proximity to the Texas border, the lack of funding in Brooks County, prior to 2013, meant that undocumented migrants were not sent to a medical examiner's office or for a forensic anthropological analysis. The situation in Brooks County is similar to most counties along the Texas border. Case studies will be used to illustrate the difficulties of this humanitarian issue along the United States-Mexico border.

Forensic Anthropology, United States/Mexico, Identification

A6 Sex Determination Using Discriminant Analysis of Upper and Lower Extremity Bones: A New Approach Using the Volume and Surface Area of Digital Models

Dong-Ho Eddie Kim, BSc, 222 Banpo-daero, Seocho-gu, Seoul 137-701, SOUTH KOREA; U-Young Lee, MD, The Catholic Univ of Korea, Dept of Anatomy, Coll of Med, 505, Banpo-dong, Seocho-gu, Seoul 137701, SOUTH KOREA; In-Beom Kim, PhD, The Catholic University of Korea, 222 Banpodaero Seochogoo, Seoul 137701, SOUTH KOREA; and Dai-Soon Kwak, PhD, Catholic Institute for Applied Anatomy, The Catholic University of Korea, 222 Banpodaero Seochogoo, Seoul 137701, SOUTH KOREA*

The goal of this presentation is to propose a new approach for sex determination using the volume and surface area of digital bone models.

This presentation will impact the forensic science community by revealing a new sex determination method using the volume and surface area of bones. Using this method, the ulna has the highest accuracy for sex determination (94%). When utilizing the surface area of multiple bones, the maximum accuracy rate of 99.4% was achieved.

This study analyzed 3D digital models of selected upper and lower limb bones. The volumes and surface areas were calculated and used for sex determination. In addition, discriminant analysis of the volume and surface area of the bones was performed to determine sex.

This study used 110 Computed Tomography (CT) images taken from donated Korean cadavers (55 females and 55 males) to create 3D models of the following upper and lower elements: the clavicle, the scapula, the humerus, the radius, the ulna, the innominate, the femur, the patella, the tibia, the talus, and the calcaneus. The average ages of the female and male samples were 54 years and 55 years, respectively; the average heights were 156cm and 165cm, respectively. Elements showing signs of surgery or deformity were excluded from the study. A medical image-processing program, Mimics® version 16.0, was used to construct the 3D models and determine the surface area and volume of the bones. The 3D models were constructed on the basis of the outer perimeter of the cortical bone and the inner marrow space was not expressed. There were no significant differences between the 3D models and actual bones (p=0.79). Significant sex differences were found in all bones with respect to volume and surface area (p<0.01). The order of volume was the same in female and male (femur > innominate > tibia > humerus > scapula); however, the order of the surface area was different. The largest surface area in males was the femur and in females was the innominate (p<0.01).

The accuracy of sex determination ranged from 72.3%-94.5% in univariate discriminant function analysis for single bones. Regarding the use of volume for sex determination, the radius, humerus, and ulna (in ascending order) were more than 90% accurate; meanwhile, for surface area, the humerus, clavicle, radius, and ulna (in ascending order) were more than 90% accurate. Interestingly, the ulna has the highest accuracy for sex determination (94%).

Discrimination analysis using pairs of bones was over 90% accurate when surface area and volume were used for sex determination. Of 66 combinations, 32 were more than 90% accurate when using volume. Again, the ulna showed the highest accuracy; the combination of ulna with femur, tibia, or fibula showed an accuracy of 95.7%. Regarding surface area, 38 of 66 combinations were more than 90% accurate. The combination of ulna and the clavicle or patella was 95.4% accurate. Thus, paired bones were more accurate than single bones.

When using the surface area of multiple bones, a maximum accuracy of 99.4% was achieved. The equation is as follows: (discriminant equation of surface area; female<0<male)=0.060×clavicle+0.020×scapula+0.045×humerus+(-0.049)×radius+0.093×ulna+(-0.023)×innominate+0.091×patella+(-0.052)×fibula+0.043×talus−11.548. Overall, this study shows that bone volume and surface area can be used for sex determination.

This study revealed that using the surface area for sex determination is more accurate than using volume. Surface area can be calculated regardless of the expression of bone marrow space, broadening its applicability. Study limitations include no broken and/or damaged bones can be used and the samples were limited to Korean individuals. Regardless, the derived sex determination equation using the surface area of various limb bones was 99.4% accurate. Therefore, together with the traditional sex determination methods, this equation can be used for sex determination from available CT, Magnetic Resonance (MR), or 3D scan data. Furthermore, this method is expected to automatically determine sex from existing digitized bone data and make it easier to research other populations.

Sex Determination, Bone Volume, Surface Area

A7 3D Analysis of Computed Tomography (CT) -Derived Lumbar Spine Models for the Estimation of Sex

Robert Foley, MS, Department of Radiology, USF Morsani College of Medicine, 2 Tampa General Circle STC7033, Tampa, FL 33606; Joshua M. Hazelton, BS, Department of Radiology, USF Morsani College of Medicine, 2 Tampa General Circle, STC7033, Tampa, FL 33606; Summer J. Decker, PhD, USF MCOM Dept of Radiology, 2 Tampa General Circle, STC 7033, Tampa, FL 33606; and Jonathan M. Ford, PhD*, Dept of Radiology, 2 Tampa General Circle, STC 7027, Tampa, FL 33606-3571*

After attending this presentation, attendees will more deeply understand the usefulness of 3D CT models of lumbar vertebrae in the estimation of sex from the spine. Attendees will also learn which measurements of the spine are most beneficial and which ones should be used with caution.

This presentation will impact the forensic science community by providing the results of a methodology to assist in forensic analysis, particularly in sex identification. This presentation will enhance existing research of osteological materials by adding data of a living, modern American sample with the spine *in situ*. This will provide insight into the natural spacing and orientation of the spinal components.

Sex identification is a crucial part of the forensic analysis of human remains. While the skull and pelvic bones are often the most ideal structures to use in sex estimation, the condition in which skeletal remains are found is frequently not ideal as bones may be damaged or missing.

Previous studies of the spine and sex estimation have examined the 1st cervical vertebra, 2nd cervical vertebrae, 12th thoracic vertebra, and the 1st lumbar vertebra with varying degrees of success. The hypothesis of this study was that CT-derived 3D models of lumbar vertebrae will be able to capture the unique morphologies used in determining sex in the human body. This study examined all five lumbar vertebrae in order to determine the most reliable and robust method for sex estimation. A series of 140 lumbar vertebrae complexes were acquired from CT and three-dimensionally reconstructed into volumetric models from living patients. The dataset was divided into 70 males and 70 females. Ages ranged from 20 years to 89 years old. Any individuals having additional or missing lumbar vertebrae were excluded from this study. The lumbar vertebrae (L1-L5) and the top of the sacrum were modeled and analyzed using 27 measurements and five aspect ratios for each vertebra. The data were then analyzed using the statistical package SPSS 22. All measurements with a $P<0.05$ were considered to be significant.

Bilateral measurements of the articular and transverse processes, pedicles, facets, and lamina were all compared using a paired t-test and no statistical significance between sides was found. Therefore, any bilateral measurements used in the discriminate function test were limited to the left side. A paired *t*-test was performed comparing males and females for each linear measurement and ratio. Measurements that were determined to be statistically significant were used for further analysis. A stepwise analysis method used these focus measurements to create discriminate equations for L1 though L5 individually.

For L1, five measurements (upper endplate width, upper endplate depth/middle depth ratio, left transverse process length, posterior vertebral height, and anterior vertebral height) predicted sex with 100% accuracy. For L2, five measurements (upper endplate depth, articular process width, spinous process height, lower endplate depth, and upper endplate width) predicted sex with 100% accuracy. For L3, four measurements (transverse process length, anterior vertebral height, spinal canal width, and spinal canal depth) predicted sex with 100% accuracy. For L4, six measurements (transverse process length, posterior vertebral body height/anterior vertebral body height ratio, articular process width, spinal canal width/spinal canal depth ratio, lower endplate width, and spinous process height) predicted sex with 100% accuracy. For L5, three measurements (lower endplate width, transverse process length, and superior articular process height) predicted sex with 100% accuracy.

Human remains in forensic cases are discovered and recovered in scattered, damaged, comingled, or partial states making identification more difficult for those establishing an unknown individual's biological profile. By having a modern living human data sample, investigators can utilize new reference data of any lumbar vertebrae in their quest for a positive identification. The accuracy of the sex estimation found in this study for all lumbar vertebrae reinforces the distinct dimorphism between sexes while also providing forensic practitioners with more options or tools for their analyses.

Lumbar Spine, Sex Estimation, CT

A8 Estimation of Stature From Footprints in a North Indian Population

Kewal Krishan, PhD, Panjab University, Dept of Anthropology, Sector 14, Chandigarh 160 014, INDIA; and Tanuj Kanchan, MD, Dept of Forensic Medicine, Light House Hill Road, Mangalore, Karnataka 575 001, INDIA*

After attending this presentation, attendees will understand the usefulness and methodology of stature estimation, especially from footprints, which will help them study cases pertaining to footprint evidence usually encountered at crime scenes and conduct further research in this area.

This presentation will impact the forensic science community by presenting standards and methodology for stature estimation from various footprint length measurements, which will be helpful in studying footprint evidence encountered at crime scenes.

Forensic podiatry is an up and coming branch of forensic science which deals with the collection, interpretation, and examination of the pedal evidence recovered at crime scenes. The evidence may be in the form of complete and/or partial bare footprints, shoe prints, or a series of footprints that can provide clues to the identity the perpetrator/criminal. The footprint evidence may help to provide identification by the study of individualistic characteristics and features present in the footprints and by providing clues regarding the biological profile of the criminal. The parameters of the biological profile such as stature and sex can be estimated from the size of the footprints. The present study provides correlation of stature with various lengths of the footprint and derives linear and multiple regression models for estimation of stature from these lengths. The sample for the present study is based upon 700 adult participants (500 males, 200 females) with ages ranging from 18 years to 30 years old. The standing footprints were taken from each participant using an inking method. Five footprint length measurements were taken from each subject using the length of the footprint from the anterior-most point of each toe pad to the posterior-most part of the heel impression (i.e., T1, T2, T3, T4, and T5, respectively), according to standard procedures and landmarks. Sex differences in stature and footprint measurements were calculated using a Student's t-test. Pearson's correlation coefficients were calculated between stature and various length measurements of the footprint. Stature was estimated from various length measurements of the footprint using linear and multiple regression analysis.

Mean stature of the study group was 170.30cm and 157.98cm in males and females, respectively. Footprint length at the first toe (T1) was found to be the longest on the left side in males and females. Sex differences in the length measurements of the footprints were statistically significant between males and females for the right and left feet ($p<0.001$). Statistically significant correlation coefficients ($p\leq0.001$) were found for correlation between stature and various footprint length measurements in males, females, and in the pooled sample, except for footprint length of the fourth toe (T4) in females. Thus, stature was found to be positively and strongly correlated to various footprint length measurements in both the sexes. In males, the correlation value (r) ranged from 0.653 and 0.693, while in females it was from 0.558 and 0.665. The correlation coefficient in the pooled sample ranged from 0.672 and 0.698. Thus, the pooled sample showed relatively higher values of correlation coefficients than males and females separately. The linear and multiple regression models were derived for estimation of stature from footprint length measurements in males, females, and the pooled group. Multiple regression models showed a marginally better result, but with a similar trend of accuracy as shown in the males, females, and pooled group in the linear regression analysis. When estimating stature from linear regression models involving all footprint length measurements, the Standard Error of Estimate (SEE) for females (left=3.4cm, right=3.5cm) was lower than that of males (left=4.8cm, right=4.9cm). Observations indicated that female footprints gave a better estimate of stature than did male footprints. Accuracy of stature estimation was marginally better on the left side compared to the right side.

Forensic Podiatry, Stature Estimation, Footprint Length

A9 Sexual Dimorphism in Mandibular Morphology Between Dentate and Edentate Individuals — Implications for Sex Estimation

Heli Maijanen, PhD, University of Oulu, PO Box 1000, Oulu 90014, FINLAND; Beatrix Dudzik, PhD, 250 S Stadium Hall, Knoxville, TN 37996; and Kathleen Hauther, University of Tennessee, 250 S Stadium Hall, Knoxville, TN 37920*

After attending this presentation, attendees will be informed on the morphological changes between dentate and edentate mandibles and their impact on sex estimation.

This presentation will impact the forensic science community by providing quantification of shape variables of the mandible between the sexes in the dentate and edentulous state.

The mandible has traditionally been included in metric and non-metric methods for sex estimation of the skull. The accuracy of methods is debatable, as previous research provides contradictory results depending on which methods and areas of the mandible are used.[1,2] Several studies have found significant changes in mandibular morphology due to tooth loss. Some studies have reported these changes exceed the sexual dimorphism seen in mandibular measurements.[3,4] Thus, the sex estimation of an edentulous mandible may be compromised.

The focus of this study was to identify and quantify sex-related differences in shape and size between dentate and edentate mandibles. Emphasis was placed on regions that have traditionally been used in non-metric sex estimation methods such as gonial angle, chin shape, ramus breadth, and mental eminence. The study evaluated the degree of sexual dimorphism in mandibular morphology and whether this dimorphism is retained with extreme tooth loss.

The sample consisted of 120 individuals, including males, females, dentate, and edentate, from the W.M. Bass Donated Skeletal Collection. Coordinate data were collected using a MicroScribe® G2X digitizer. Twenty-three landmarks were collected that represent morphological areas that are typically used in sex estimation methods. Shape-related differences of dentate and edentulous samples were examined congruently with metric dimensions. Additionally, quantification of shape variables associated with the mental eminence was approximated by the use of a new combination of landmarks, including a novel landmark that makes visualization of shape variation among males and females more feasible when alveolar resorption has occurred.

Preliminary results showed significant differences between males and females in the dentate group in three measurements: bigonial diameter, bicondylar breadth, and mandibular length. All these measurements were greater in males. The differences were smaller in the edentate group. In both males and females, the gonial angle was wider in the edentate group, but no significant sex differences were found in either group. Comparison of shape coordinates of dentate males and females showed significant differences and provided higher accuracy in discriminant analyses than has been reported in previous studies. Differences in the sexes among the edentulous sample were not as significant as with the dentate cohort; however, accuracy estimation percentages were near 80%.

The results confirm the earlier findings that there are changes in mandibular morphology due to tooth loss. These changes seem to diminish the sexual dimorphism seen in dentate individuals in certain areas; however, when shape variables are examined, higher estimation accuracies can be obtained. These results indicate that quantified shape variables should be taken into account if sex estimation from isolated dimensions of an edentate mandible is attempted.

Mandibular Morphology, Sex Estimation, Tooth Loss

A10 Evaluating Elongated Pubic Bones as a Potential Sexing Method for Juveniles

Cassie E. Skipper, BS, Texas State University, New Braunfels, TX 78130*

After attending this presentation, attendees will be informed about the issues with current subadult sexing methods and the utility of public bone elongation as a sex indicator in juvenile skeletal remains and its relationship with age.

This presentation will impact the forensic science community by helping to make sexing juveniles a simpler and more realistic task than it currently is, which will aid in identification and the return or curation of unknown remains.

In the field of anthropology, it is important to know the biological profile of individuals in order to understand past population structure, mortality rates, sex-specific burial practices and rituals, and demographics of study samples and populations. This information is critical to increase insight into archaeological populations and to establish standards for research techniques.

Specifically in biological anthropology, having enough information and applicable methods to estimate the biological profile from skeletal remains is imperative for the identification of unknown individuals. Current literature on juvenile sexual dimorphism is lacking, and existing publications on juvenile sexing methods have been known to result in low correct classification rates.[1] Furthermore, Holcomb and Konigsberg attest to a wide overlap between the two sexes and question the accuracy of current sexing methods in juveniles.[2] These issues lead to the hindrance of juvenile sex estimation analyses and the identification process. Cognizance of sexual dimorphism patterns and human variation within and between populations is important in order to produce a stronger academic and research foundation for the field and their resulting real world applications.

Bass noted the elongation of the pubic bone as being a female trait.[3] This trait is often informally recognized by biological anthropologists, but it is seldom officially identified and used in non-metric trait studies. As of yet, pubic elongation and radiographic images of juvenile pubic bones have not been utilized as a potential method to quantify sexually dimorphic traits in subadults.

The present research includes a preliminary evaluation of juvenile pubic bones for sexual dimorphism. Radiographs of 20 juveniles from 9 years to 12 years of age were selected at random from the Pediatric Radiology Interactive Atlas (Patricia®) database.[4] Each individual was scored three times for presence/absence of elongated pubic bones. Three rounds of scoring were used to ensure reliability of this method and to serve as intra-observer error for future research in this study.

Chi-square goodness of fit and Cramer's V statistics were employed to evaluate the significance of the results. Sex (X^2=10.769, p-value=0.001; Cramer's V=0.734, p-value=0.001) was found to have a stronger correlation with the presence of elongated pubic bones than age (X^2=6.848, p-value=0.039; Cramer's V=0.569, p-value=0.039). Females under the age of ten years used in this research were incorrectly classified as male based on their lack of pubic elongation.

Preliminary findings indicate that this method accurately classifies males aged 9 years to 12 years old and females aged 10 years to 12 years old. Other methods for sexing juvenile skeletal remains are often unreliable, inconsistent, and/or require extensive amounts of data and funding. The method proposed here is less expensive and more efficient than established methods and can have a profound effect on the identification rates of unknown juveniles.

Juvenile Skeletons, Sex Estimation, Pubic Bone

A11 Age Estimation Using the Sternal End of the Clavicle: A Test of the Falys and Prangle Archaeological Method for Forensic Application

Meghan Price, Boston University School of Medicine, 72 E Concord Street, Boston, MA 02134; James Pokines, PhD, Boston University School of Medicine, Dept of Anatomy & Neurobiology, 72 E Concord Street, L1004, Boston, MA 02118; and Jonathan D. Bethard, PhD, Boston University School of Medicine, Dept of Anatomy & Neurobiology, 72 E Concord Street, L1004, Boston, MA 02118*

After attending this presentation, attendees will understand the reliability of a new age estimation method designed to increase the accuracy of aging individuals who were more than 40 years of age.

This presentation will impact the forensic science community by emphasizing the need for and application of age estimation methods that accurately age older individuals. This presentation discusses a new method for estimating age from the sternal end of the clavicle, as described in Falys and Prangle and tests this age estimation method on a modern American sample.[1]

Age estimation is a critical component of the biological profile in forensic and bioarchaeological contexts. The majority of these methods are most accurate for individuals of younger age cohorts, typically those less than 40 years of age. Skeletal degeneration can vary greatly between individuals, making age estimation less accurate for adult individuals. While there are some methods that attempt to age older individuals accurately and precisely, more research must be conducted to expand the range of methods available. Falys and Prangle developed a method for estimating age in individuals who were more than 40 years of age using three characteristics of the sternal end of the clavicle: (1) surface topography; (2) porosity; and, (3) osteophyte formation.*1*

In order to test their method, a sample of 1,510 individuals of known sex and age, ranging from 20 years to 101 years of age (males: *n*=1,112, mean=50.57, Standard Deviation (SD)=18.015; females: *n*=398, mean=53.065, SD=20.358), were drawn from the McCormick Collection and the William M. Bass Donated Skeletal Collection at the University of Tennessee.

The two estimation methods proposed in Falys and Prangle, regression equation and composite score, were tested to see how well they performed when applied to the collected data.[1] When applied to the collected data, the regression equation produced age estimations within the 95% confidence interval in 47.6% of the male sample and 57.4% of the female sample. Composite scores were calculated and compared to the corresponding age ranges provided by Falys and Prangle.[1] The composite scores of the male sample estimated the age of an individual more accurately than the composite scores of the female sample (male=65.9%; female=58.8%). The lowest estimation accuracy for both males and females was between 70 years to 79 years of age (male=46.0%; female=51.4%). From 80 years to 89 years of age, the accuracy increased for males (76.4%) and females (69.4%).

The sample also included individuals less than 40 years of age in order to test the applicability of this method. Multiple regression equations were generated: (1) individuals more than 20 years of age; (2) individuals less than 30 years of age; and, (3) individuals more than 40 years of age. The results from the multiple regression analyses show comparable Pearson's coefficients for the above-mentioned equations (r=0.690, r=0.632, r=0.611, respectively).

Spearman's rank correlation coefficients indicated a correlation significant at the 0.01 level for all three components individually, as well as the composite score. Of the three components, surface topography was most strongly correlated with age for both males (r=0.643) and females (r=0.590). Unlike the findings of Falys and Prangle, porosity was found to be the least correlated with age for both males (r=0.474) and females (r=0.514).[1] In addition, when broken down into ten-year intervals (40-49, 50-59, etc.), the correlation coefficients increased with advancing age. This suggests that the method becomes more accurate as the age of an individual increases.

The findings in the present study indicate that the sternal end of the clavicle has potential for use in age estimation in older individuals. Although the present study produced lower correlation coefficients than proposed by the original study in 2014, the results suggest this method has the potential to provide accurate and precise age ranges for older individuals.

Age-at-Death Estimation, Clavicle, Forensic Anthropology

A12 Accuracy of Dental Age in Non-Adults: A Comparison of Two Methods for Age Estimation Using Radiographs of Developing Teeth

Sierra Santana, BA, Boston University School of Medicine, 72 E Concord Street, Boston, MA 02118; Jonathan D. Bethard, PhD, Boston University School of Medicine, Dept of Anatomy & Neurobiology, 72 E Concord Street, L1004, Boston, MA 02118; and Tara L. Moore, PhD, 700 Albany Street, W701, Boston, MA 02118*

After attending this presentation, attendees will better understand the principles of estimating age in non-adults, current methods that utilize radiographs for age estimation, and their application to the forensic and legal communities.

This presentation will impact the forensic science community by expanding knowledge of the current methods for estimating age in non-adults using dental radiographs by providing a comparison of two dental age estimation methods outlined in Cameriere et al. and AlQahtani et al.[1,2]

Estimating age at death of an individual is an important factor within several scientific fields, with direct application to forensic, archaeological, and legal settings. The goal of this presentation is to provide an assessment of the accuracy and applicability of two recently published methods for age estimation in non-adults, Cameriere's European formula for age estimation and AlQahtani's London Atlas on a multi-ethnic American population.[1,2] These two methods are of particular interest because initial research demonstrates that these methods may produce a more accurate and precise age estimate than the methods currently used in the field of forensic anthropology.[3]

This study utilized dental radiographs drawn from the Maxwell Museum of Anthropology's Orthodontics Case File System at the University of New Mexico. The sample consisted of 363 panoramic radiographs from individuals aged 7 years to 17 years old (mean age=11.9 years) with each individual having been identified as having affiliation with one of the following ethnicities: American Indian, Hispanic, or White/European American. A Dental Age (DA) estimation was performed for every radiograph twice, once using the method outlined by Cameriere and once using the London Atlas. The Chronological Age (CA) of each individual is calculated as the difference between the date of birth provided in the dental record and the date on which the radiograph was taken. For each method, accuracy and bias were determined. The accuracy of DA estimation is defined as how closely CA can be predicted. Bias is defined as the mean difference between DA and CA and can be either a positive or negative number and is used to determine if a method overestimates or underestimates an individual's age. Furthermore, categories relating to ethnicity, sex, and age were applied to the assessment of accuracy and bias in order to compare the two methodological approaches.

The age of each individual was calculated as the difference between the date of birth provided in the dental record and the date on which the radiograph was taken. Preliminary statistics demonstrate a significant positive correlation ($p<0.01$) between DA and CA for both the London Atlas ($r=.87$) and Cameriere's ($r=.72$) method.

To test intra-observer reproducibility, a random sample of 40 panoramic radiographs was re-examined after an interval of two weeks and tested using Pearson's correlation coefficient. Results indicate that there were no statistically significant intra-observer differences between the paired sets of measurements carried out on the re-examined panoramic radiographs for either method.

Estimated age was closer to CA using the London Atlas than Cameriere's method. The London Atlas underestimated age by approximately 0.12 years (Standard Deviation (SD)=2.3) for males and 0.21 years (SD=2.8) for females. Cameriere's method underestimated CA by approximately 1.43 years (SD=1.64) for males, 1.76 years (SD=1.64) for females. In regard to true age, the mean CA was 11.99 years for girls, with Cameriere's method producing a mean DA of 10.23 years and the London Atlas producing a mean DA of 11.76. For boys, the mean CA was 11.95 years with the mean DA being 10.40 years for Cameriere's method and 10.23 years for the London Atlas. Both methods underestimated CA for both sexes. Furthermore, in regard to Cameriere's method, it is suggested that a new regression formula specific to an American population should be created.

Age Estimation, Non-Adult, Dental Radiograph

A13 A Test of Cervical Vertebral Ring Union for Age-at-Death Estimation Using the Albert-Sherwood Method

A. Midori Albert, PhD, University of NC Wilmington, Dept of Anthropology, 601 S College Road, Wilmington, NC 28403-5907; and Kate D. Sherwood, 10401 Litzsinger Road, St. Louis, MO 63131*

After attending this presentation, attendees will gain a more in-depth understanding of the applicability of the Albert-Sherwood vertebral ring epiphyseal union method for estimating the age of unknown skeletons. This presentation seeks to explain how the method may be applied, reports on its accuracy, for cervical vertebrae, and suggests contexts for its considered use in age estimation.

This presentation will impact the forensic science community by demonstrating how a specific skeletal age estimation method may be used and by explaining the meaningfulness and utility of the results that may be obtained. Information presented here may serve forensic anthropology practitioners as well as researchers interested in the further study of this approach to age estimation.

The purpose of this study was to test the accuracy of estimating age at death by examining the progress of cervical vertebral maturation using epiphyses of the centra that were in poor condition to simulate real-world forensic contexts. Further, another goal of this study was to test the accuracy of estimating age at death on a sample derived from a population differing from the reference/guideline sample. Ages were estimated using cervical vertebral data originally collected from a population differing from the test sample since in the practice of forensic anthropology there are often issues with applying guidelines developed on one sample but used for another — inasmuch as different samples may be affected by cross-population variability and or secular changes in skeletal growth, development, and degeneration.

The test sample for this study was derived from the Lisbon Collection housed at the Museu Nacional de História Natural, Museu Bocage in Lisbon, Portugal. It contained vertebrae that were deteriorated, damaged, and/or characterized by fragile epiphyseal rings. The test sample comprised 20 individuals (7 female, 12 male, and 1 individual of indeterminate sex), ranging in age at death from 10 years to 30 years old; however, the sex and age at death were unknown at the time the aging method test was conducted (i.e., this was a blind study). Due to the discovery of 1 of the 20 individuals not having any cervical vertebrae available for analysis, the final test sample included 19 individuals.

Guidelines used to estimate the ages at death for the test sample were developed from vertebral ring union data obtained from the Hamann-Todd Osteological Collection housed at the Cleveland Museum of Natural History in Ohio. The guideline sample comprised 100 individuals between the ages of 10 years to 30 years old at death: 55 African Americans (34 females and 21 males) and 45 European Americans (19 females and 26 males). The sample was selected by sorting the collection according to sex and age at death, and individuals were randomly selected for each age in years to ensure continuous representation of the maturation process, as much as possible. The progress of cervical vertebral ring union was documented in five stages (i.e., the Albert-Sherwood method, revised from the Albert-Maples method): (1) Stage 0 was no union; (2) Stage 1 was beginning and active union; (3) Stage 2 was complete union with no remodeling of the gaps between the epiphysis and centrum; (4) Stage 3 was complete union with some (incomplete) remodeling of the gaps; and, (5) Stage 4 was complete union with complete remodeling (note: this stage may not be attained in all vertebrae as occasionally a "scar" remains). The guidelines for age estimation, based on this five-stage method, include key ages at which the stages of vertebral ring union are first attained (Stages 0-4), at what ages they are sustained (Stages 0-4), and/or the ages at which they are surpassed (Stages 0-3; Stage 4 is the final stage and if/when attained, it persists).

Ages were estimated by comparing the test sample stages of union for each individual (age and sex unknown during this part of the study) with the guidelines for the earliest and latest ages for various stages of union. Since sex differences were found to exist when the guidelines were developed, not knowing the sex during the test of the method yielded wider intervals of estimated ages. Results indicated that age estimation intervals were correctly assessed for 16 out of 19 individuals (84%), spanning ages 10 years to 30 years old. For the three individuals incorrectly assessed, they were estimated to be no older than 10 years of age; however, the actual ages were 13 (one male) and 14 years (two males). This finding suggested that ring epiphyses may have broken off, giving the appearance of bare centra for which no epiphyseal union had begun, but in reality may have been in progress or it could be that maturation may simply begin later in the population from which the test sample was derived. Further details of the findings and their implications for the utility of this method are discussed. Overall, this method is promising for use in the field, particularly in conjunction with other skeletal age indicators and when sex can be adequately assessed.

Vertebral Maturation, Age Estimation, Epiphyseal Union

A14 Age Estimation Using Osteophytic Activity on the Lumbar Vertebrae and Partial Least Squares Regression

Jacob Griffin, BS, 16665 Danville Road, Danville, IA 52623; and Stephen D. Ousley, PhD, Dept of Anthropology/Archaeology, Mercyhurst University, 501 E 38th Street, Erie, PA 16546*

After attending this presentation, attendees will better understand how to estimate the age at death of adult individuals using osteophyte development on the vertebral centra and the utility of the prediction intervals presented in the methodology.

This presentation will impact the forensic science community by presenting a method that can be used to estimate the age at time of death of adult individuals when only the lumbar vertebrae are present. This presentation also shows the need to continue further studies into the utility of osteophytes for biological profile estimation, for they are an area with very little previous research.

Historically, there have been four areas that are typically used for adult age estimation.[1] These areas include the auricular surface, sternal rib ends, pubic symphysis, and cranial sutures. Other areas of the skeleton have been investigated with the same scrutiny. One area that has received very little attention is the osteophytic activity on the vertebral column. These osteophytes are frequently used to obtain general age estimations when employing the *Gestalt* method of getting a feel for the age of the decedent based upon the morphological appearance of several areas; however, there has been little work performed to develop quantitative or qualitative adult age estimation methods using osteophytosis since the work of Stewart.[2,3]

Snodgrass continued research into osteophyte development on the vertebral centra using revisions made to the Stewart scoring system.[3,4] Snodgrass used inappropriate statistics for ordinal data and his method is difficult to apply due to a lack of description and illustration.[4] It is difficult to apply the developed scoring system to osteophytic development, especially for those with a limited understanding of the developmental patterns of osteophytes on the vertebral centra.

A total of 203 White males and females of known ancestry, sex, and age were sampled from the Hamann-Todd Collection at the Cleveland Museum of Natural History. The superior and inferior rims of each lumbar vertebra were scored using the Snodgrass five-stage, ordinal scoring system.

Polychoric correlation matrixes showed there is a high degree of correlation between the superior and inferior rims of all five vertebrae. The highest correlation found between two vertebrae was 0.92 and the lowest correlation was 0.69. The polychoric correlation also found that the variables are all highly correlated and, thus, multicollinearity is an issue. Analysis of Covariance (ANCOVA) showed that the differences between the mean scores for males and females across age were not statistically significant with an F-value of 0.429. Partial least squares regression was chosen for age estimation over other methods because it eliminates the problem of multicollinearity. The partial least squares model was then used to create 95% prediction intervals using R software.[5]

The 95% prediction intervals reported in this presentation are quite large with the interval being approximately 50 years. Many forensic anthropologists argue that this method is of little use in narrowing down the missing persons list due to its large age intervals; however, the lower bounds of these intervals do provide important cut-off points. For example, if an individual scores a three on all of the vertebral rims, the observer can conclude, with 95% confidence, that he or she is more than 46 years of age. This finding can eliminate a large portion of possible identifications and would be useful when combined with other age estimation methods. Osteophytosis can be used as a method for age estimation, but it does require further research and validation. Revisions need to be made to the scoring system developed by Snodgrass.

Age Estimation, Osteophytes, Vertebrae

A15 The First Thoracic Vertebral Centrum as an Adult Age Estimation Site

Kristina B. Altes, MA, CA Pound Human Identification Laboratory, 2033 Mowry Road, Rm G-17, Cancer/Genetics Research Complex, U of FL, Gainesville, FL 32610*

After attending this presentation, attendees will be aware of a new adult age estimation site that may supplement current sites, such as the pubic symphysis and sternal rib ends.

This presentation will impact the forensic science community by providing a new adult age estimation site when others are unavailable in skeletal remains.

The thoracic vertebrae have received relatively little attention as age estimation sites compared to the pelvic joints, the ribs, and the cranial sutures. Albert and Maples established juvenile and young adult age estimates based on annular epiphysis fusion, while Stewart and Snodgrass found correlations between osteophyte development and adult age; however, none of these studies focused on specific vertebrae, and none have attempted to provide a "gestalt" description of the aging thoracic centrum.[1-3]

Photographs of the inferior centra of 168 undamaged first thoracic vertebrae from the Robert J. Terry Anatomical Skeletal Collection at the Smithsonian National Museum of Natural History were examined. The sample consisted of 48 White males, 44 Black males, 37 White females, and 39 Black females. The inferior aspect of first thoracic vertebra centra were assigned to one of five phases defined by degree of epiphyseal ring obliteration, texture, symmetry, and edge irregularity. Inter-observer error was assessed by using 14 first thoracic vertebrae from the C.A. Pound Human Identification Laboratory (CAPHIL) archives. The same vertebrae were scored one week later to assess intra-observer error. Similar tests of error were performed using the Brooks and Suchey method on 14 left pubes, also from the CAPHIL archives, for comparison.[4]

Age correlated with phase relatively well within the pooled sample (R^2=0.25) and even better when sex was considered separately (R^2=0.27 for males and 0.30 for females). An Analysis of Variance (ANOVA) test demonstrated that phases differ significantly from one another in mean age (p=2.39x10^{-10}), while a Games-Howell post-hoc test demonstrated that Phases 1 and 2 differed significantly from Phases 4 and 5; Phase 3 from Phase 5; Phase 4 from Phases 1, 2, and 5; and Phase 5 from all other phases. In addition, inter- and intra-observer errors were smaller when using this method than when utilizing the Suchey-Brooks pubic symphysis method: inter-observer kappa for the thoracic vertebrae was 0.51 and 0.70, indicating moderate and substantial agreement between observers, respectively. In contrast, inter-observer kappa was 0.30 for each pair of inter-observer comparisons for the pubic symphyses, indicating fair agreement. Intra-observer kappa was 1.0 for the thoracic vertebrae and 0.83 for the pubic symphyses, indicating perfect and almost perfect agreement, respectively.

These results suggest the first thoracic vertebral centrum may be a useful adult age estimation tool, in addition to more commonly utilized joint surfaces. Future research will develop this method more thoroughly on a more modern population.

Forensic Anthropology, Age Estimation, Vertebrae

A16 Improved Adult Age Estimation Using New Skeletal Traits and Transition Analysis

George R. Milner, PhD, Department of Anthropology, 409 Carpenter Bldg, Pennsylvania State University, University Park, PA 16802; Jesper L. Boldsen, PhD, ADBOU, Institute of Forensic Medicine, Lucernemarken 20, 5260 Odense S, DENMARK; Stephen D. Ousley, PhD, Dept of Anthropology/Archaeology, Mercyhurst University, 501 E 38th Street, Erie, PA 16546; Svenja Weise, PhD, Institute of Forensic Medicine, University of Southern Denmark, Odense, DENMARK; Sara M. Getz, MS, Penn State University, Dept of Anthropology, 409 Carpenter Bldg, University Park, PA 16802; and Peter Tarp, MS, Institute of Forensic Medicine, University of Southern Denmark, Odense, DENMARK*

After attending this presentation, attendees will better understand new directions in age estimation for adult skeletons, as well as preliminary results from a National Institute of Justice (NIJ) grant that involves an integrated approach featuring new skeletal age markers, analytical methods, and computer program development.

This presentation will impact the forensic science community by highlighting ongoing progress made in improving the accuracy and precision of adult skeletal age estimation methods, focusing on the use of better-defined skeletal features, statistically sound methods, and software to aid in recording and analyzing age-informative skeletal markers.

Accurate age-at-death estimates are essential in forensic identifications from skeletal remains. Yet despite a century of research, accurate and precise age estimates are beyond what standard methods employed by forensic anthropologists can provide, especially for individuals older than approximately 45 years of age. Estimates of age have traditionally incorporated information from the cranium, pubic symphysis, and sacroiliac joint. Unfortunately, these areas only yield information about the first few decades of adulthood and are often so variable among individuals that they fail to yield satisfactory estimates. Age estimates spanning decades contribute little or nothing to narrowing possible identifications. Only recently have age estimation methods incorporated advanced statistical methods, such as transition analysis.[1]

Standard age estimation procedures suffer from poor reliability (low agreement between observers in feature scores), low precision (large age estimation intervals, frequently "eyeballed"), and poor accuracy (agreement between estimated and actual age), problems that have been recognized in bioarchaeology for more than three decades.[2] Commonly used procedures also have open-ended terminal intervals (e.g., 50+ years), rendering them worthless for identifying elderly people. These problems have made adult age estimation one of the biggest challenges for forensic anthropologists, especially in the post-*Daubert* era.

Fortunately, the situation is not as bleak as might be imagined.[3] A recently awarded NIJ grant builds on promising pilot studies to develop a procedure that incorporates three interrelated and essential features: (1) the definition of new skeletal traits and the collection of data on their ages of transition; (2) the incorporation of mathematical approaches to properly analyze age-related information; and, (3) the development of a computer program that will enable practitioners to make effective use of the new skeletal information and analytical procedures. In short, substantive improvement requires a thorough rethinking of what is examined, how skeletal traits are used, and the production of a computationally heavy but user-friendly computer program. To have a major impact on forensic investigations, all three tasks must be completed simultaneously. This initiative is part of a broader trend in osteological research that owes inspiration to *Daubert* guidelines for reliable and valid age estimates, coupled with greater accuracy, explicit prediction intervals, and greater applicability to diverse populations.[4]

Preliminary results derived from more than 400 individuals from the Universities of Tennessee and Pretoria show that the new approach produces better results than commonly used procedures. Many parts of the skeleton, not just a few parts, are informative about age. Traits have been investigated in all major long bones, ribs, vertebrae, pelvis, skull, and select bones of the hands and feet. Valuable age-informative transitions have been derived for traits in many of these areas, including the humerus, femur, sacrum, and other areas on the innominate. When ages of transition from several features are combined, they show how skeletal traits that are rarely, if ever, used in existing methods measurably enhance the accuracy and precision of age estimates throughout adulthood. These preliminary results, based on only part of the eventual total sample, were compared to the limited information that can be gleaned from the pubic symphysis and sacroiliac joint, the parts of the skeleton most commonly used for age estimation. The new features perform better for age estimation than those areas.

The main preliminary results show that age-informative markers are distributed throughout the skeleton, they can be analyzed to provide information about age throughout the adult lifespan, and the predicted ages are more accurate, precise, and replicable.

Age Estimation, Transition Analysis, Skeleton

A17 Effects of Scavenging Birds and Insects on Decomposition Time of Pig Carcasses at the Rice Creek Field Station

Brianna L. Robinson, 112 Ketchum Road, Conklin, NY 13748; and Kathleen A.S. Blake, PhD*, State University of NY at Oswego, Dept of Anthropology, Mahar 441, Oswego, NY 13126*

After attending this presentation, attendees will better understand the role of avian scavenging during the decomposition process and how presence and timing of avian species differs between seasons in upstate New York.

This presentation will impact the forensic science community by providing an understanding of how avian species, habitat, and temperature ranges in the Northeast have different impacts on scavenging and carrion preservation levels. This presentation will add knowledge to an area of little research pertaining to avian scavengers and their impact on decomposition particularly in upstate New York.

A few studies have focused on avian scavenging or briefly discussed their contribution to the decomposition process; however, this subject has been severely understudied in the temperate Northeast.[1-4] Compared to mammals, avian carnivores are known to be more adapted with their abilities to scavenge for carrion.[5] The effect of this region's climate and geography both play a role in the type of scavengers seen.

For this research, four separate 10'-diameter plots of 2"x4" mesh fencing were placed throughout the grounds at two different environmental locations in Rice Creek Field Station at the State University of New York at Oswego, NY. The control plot fencing was covered with bird netting to allow for natural decomposition without the effect of any scavengers. One pig (*Sus scrofa domesticus*) carcass was placed in each plot during the autumn of 2014 and the spring of 2015 (n=8). The two environments were open grassland and woodlands, both with an accompanying control. The autumn experiment ran from October 1 until December 1 and the spring experiment was from March 2 until late May. During decomposition, wildlife cameras were set out and checked weekly during midday hours.

The fall experiment pigs were predated on by a single avian species, turkey vultures. Maggots dominated the percentage of insect activity and had the most effect on decomposition. Vultures visited both the open and wooded experimental sites for only week two of the project. The average feeding time for vultures was 28.7 minutes over the course of five days. Observations found all pigs decayed by 80% within four weeks of placement. Insects primarily affected the rate of decomposition, with scavenger activity minimal. Insect activity was focused on the head and shifted downward as decomposition progressed.

The spring experiment results showed a 100% species variety increase and 193% increase of scavenging individuals. Red-tailed hawks and vultures were both seen within a few days of placement. Vultures continued to visit the forest site past week six of decomposition. The average feeding time for avian species in the spring was 30.8 minutes over the course of 19 days. The damage and scavenging done by avian species was higher by 800% in the spring but still did not heavily affect decomposition. Decay was delayed substantially, with no signs present within the first four weeks due to colder weather conditions in the spring. All pigs that were predated upon were scavenged mostly in three specific locations; these included the anal region, head, and torso.

This study's findings differ from others, particularly a study in Texas, which found that black vultures and turkey vultures completely skeletonized the pig in 3 to 27 hours of arrival.[6] A case in southern Illinois, on the other hand, observed a delay in the time of first arrival of the vultures but still found complete skeletonization within two months.[2] This study found that scavenging was minimal with no complete skeletonization from avian species in either season.

In conclusion, this study provides evidence that while avian species may be present during the decomposition process, they may not heavily impact the rate of decay. Seasonal changes in the environment affected the abundance and variety of avian species seen at each site as well as insect activity present. Furthermore, data gained from this research can be used to illuminate the differences from other regions as well as caution that scavenging data from these areas cannot be applied to the Northeast.

Scavenging, Decomposition, Taphonomy

A18 The Mummy in the Microwave: The Efficacy of the Microwave Method for the Maceration of Desiccated Tissue

Christiane Baigent, MSc, Metropolitan State University Dept Sociology/Anthr, PO Box 173362, Campus Box 28, Denver, CO 80217-3362; and Gary T. Scott, MA*, Metropolitan State University of Denver, Dept of Anthropology and Sociology, 1201 5th Street, Campus Box 28, Denver, CO 80204*

After attending this presentation, attendees will better understand decomposition as an important variable when selecting a maceration method and specifically, how the efficacy of the microwave technique is interrupted by desiccated tissue.

This presentation will impact the forensic science community by presenting observations made in a controlled laboratory environment on a subject for which little published data exists. Further, desiccation is considered on a molecular level and introduced as a new variable for consideration when selecting a method for tissue removal.

The maceration of human remains in the forensic anthropology laboratory has received variable attention in the literature. For logical reasons, an early emphasis was placed on the preservation of bone composition and gross morphology. More recently, the focus has shifted to the effect of various maceration techniques on nuclear DNA preservation and the preservation of microstructures associated with traumatic lesions.[1-3] Among the suite of methods tested in these studies is the microwave technique, in which skeletal elements are placed in a microwave-safe dish, loosely covered with a lid or plastic wrap, and microwaved on high for one-minute intervals until all soft tissue "easily slip[s] from the bones."[1] The use of both *Sus scrofa* and human bone and associated soft tissue is reported in the literature with consistent positive results. Absent from these studies is a discussion regarding decomposition as a variable and the potential for its many stages to differentially affect the efficacy of a maceration method. Because it has been lauded for its ease of use, and tested positively in the preservation of both DNA and the micro-morphology of osseous lesions, the microwave method was selected for use in a recent analysis conducted by the Metropolitan State University of Denver Human Identification Laboratory (MSUD-HIL). This presentation reports the results of the use of the microwave method in a case in which overlying soft and connective tissue structures were present in various stages of desiccation.

The skeletal elements associated with the left shoulder girdle, arm, and hand of an adult male were recovered from a high-altitude outdoor site north of Denver, CO. Desiccated dermal and connective tissue was present and mummification was observed in the hands, characterized by the preservation of all dermal layers and integumentary accessories (nails, eponychium, and hair). Prior to processing these remains, the technique was performed on eight *Sus scrofa* ribs; the results of preliminary processing were consistent with published data. The human remains were then processed in the MSUD-HIL. Bones were sequentially placed in a glass dish containing 2mm of water and covered with plastic wrap, then heated using a microwave (2.2 cu. ft., 1,250W) set on high for one-minute intervals. The process was numerically scored following Steadman et al. to quantify odor, soft tissue texture, ease of tissue removal, and bone quality.[1] The resultant bone quality scores were consistent with published results, but odor, tissue texture, and ease of tissue removal (and subsequent processing time) varied greatly from published scores. Additionally, scores between skeletal elements varied greatly, with the clavicle demonstrating the greatest ease of tissue removal and the scapula and carpals presenting the most difficulty.

The results suggest the structural changes associated with dehydrated cartilage and connective tissue has a substantial effect on the maceration of human remains and should be considered prior to engaging in tissue removal. Zhu and Fang report that the nanostructure of dehydrated cartilage is characterized by inhomogeneous fibril D-periodic spacing (decreased tissue organization), increased fibril diameter (greater bulk and density), and an increase in surface rugosity (with attendant changes in surface area expected).[4] These structural changes proved to be reversible during laboratory rehydration, making it is reasonable to suggest that the added process of rehydration affects maceration time as the distance from the denaturation threshold is increased. The increased processing time may have bearing on extant concerns surrounding DNA recovery and analysis and the preservation of trauma morphology, indicating that desiccated tissue should be regarded as a significant variable in the maceration process. Therefore, further testing is recommended to address tissue removal throughout the continuum of decomposition. While these observations do not outweigh the empirically tested benefits of the microwave method, they do suggest that more careful consideration is warranted.

Microwave Maceration, Desiccation, Mummification

A19 The Effect of Plastic Tarps on the Rate of Human Decomposition During the Spring/Summer in Central Texas

Chloe P. McDaneld, 125 Amberwood Cove, Kyle, TX 78640; and Daniel J. Wescott, PhD, Texas State University, Dept of Anthropology, 601 University Drive, San Marcos, TX 78666-4684*

After attending this presentation, attendees will gain a better understanding of decomposition rates of human remains wrapped in tarps and whether they are different than unwrapped human remains using Total Body Scores (TBS) and Accumulated Degree Days (ADD).

This presentation will impact the forensic science community by adding to the research on the effects of decomposition when the body is covered or wrapped in a tarp. It will also contribute to time-since-death estimation.

Forensic case reports cite that bodies are commonly covered or wrapped in man-made materials for disposal and concealment.[1-3] Therefore, knowing whether there are differences in the rate of decomposition between wrapped and unwrapped bodies is important for forensic scientists conducting estimations of time since death. While several studies have been conducted on the effects of decomposition when the body is covered or wrapped in materials such as clothing, blankets, and plastic tarps, most of these studies have examined a variety of coverings simultaneously with relatively small sample sizes.[4-9] Therefore, the purpose of this study was to conduct a controlled investigation of the effect of plastic tarps on the rate and pattern of decomposition in Central Texas using a relatively large sample size. Unlike previous studies, this study utilized only one type of covering, the sample size was larger than previously examined, and environmental conditions and dates of death were known.

Human remains covered or wrapped in a tarp provide the perfect environment for decomposition since the tarp may maintain moisture and temperature while providing insects and bacteria protection from the sun and rain. Therefore, it was hypothesized that the plastic tarp would aid in decomposition in two ways: (1) by increasing the activity of necrophagous insects, which prefer a warm, shaded, and outdoor environment; and, (2) by increasing putrefaction caused by bacteria that require an aqueous medium.[10-12] The increased activity of insects and bacteria would therefore likely increase the rate of decomposition or, in other words, require fewer ADD to reach each stage of decomposition.

The study sample consisted of 20 bodies wrapped in plastic tarps and a matched control sample of unwrapped bodies, both placed on the ground surface in a tree-covered area of the Forensic Anthropology Research Facility at Texas State University. The TBS was compared between the wrapped and control bodies at 500 ADD and 1,000 ADD.[13] *T*-tests were used to test for statistical significance.

Statistical analyses showed that tarps primarily have an effect on the rate of decomposition after 500 ADD. There were no significant differences in TBS between the human remains wrapped in plastic tarps and the unwrapped remains at 500 ADD (p-value=.118036). While the rate of decomposition was not significant, it was observed that for the bodies wrapped in tarps, the head and neck region decomposed faster (higher TBS) compared to the control group; however, at 1,000 ADD, there was a significant difference in TBS between human remains wrapped in plastic tarps and the unwrapped remains (p-value=.0456).

The results show that during the early decomposition period, plastic tarps do not have a significant effect on the rate of decomposition, but the tarp may affect the observed pattern of decomposition. As the decomposition process continues, insect activity associated with the unwrapped bodies decreased and the bodies began to desiccate; however, the consistent warm and shaded environment in the tarps allowed for continued insect activity and slowed desiccation. As a result, bodies wrapped in plastic tarps had a greater TBS after 500 ADD than unwrapped bodies. These results suggest that ADD calculations based on TBS may underestimate the time since death for a body wrapped in a tarp if the individual has been deceased for more than 500 ADD.

Human Decomposition, TBS, Tarps

A20 Effect of Body Size on the Rate of Outdoor Human Soft Tissue Decomposition

Lindsey G. Roberts, MA, 912 E Cindy Street, Carbondale, IL 62901; and Jessica R. Spencer, MA, 424 S Front Street, Cobden, IL 62920-2415*

After attending this presentation, attendees will understand the effects of body size on the progression of outdoor human soft tissue decomposition.

This presentation will impact the forensic science community by contributing to a greater understanding of a key variable affecting decomposition and the estimation of Postmortem Interval (PMI).

This research examined differences in the decomposition rate of human subjects with respect to body size. Previous studies have primarily focused on animal models, and yielded conflicting results concerning the impacts of body size on the rate of decomposition, with some suggesting no effect, while others found subject mass to be a key factor in which smaller subjects progressed more rapidly through decomposition than larger subjects, and yet another found mass to differentially affect decomposition depending on the stage of decomposition.[1-6] Due to the liquefaction of adipose tissue and the results of previous studies, this research hypothesized that larger subjects would decompose more rapidly during early decomposition (6.0≤Total Body Score(TBS)<19.0) but less rapidly during advanced decomposition (19.0≤TBS<27.0).[6-7]

Eleven human subjects donated to the Complex for Forensic Anthropology Research (CFAR) at Southern Illinois University (SIU) were placed unclothed, supine, directly on the ground surface within the complex between December 7, 2012, and March 3, 2015. Subjects were placed between 2m-25m apart, resulting in almost identical research environments, and protected from avian and mammalian scavengers by chain-link cages. Subject samples included eight males and three females between the ages of 49 years and 95 years with the following body weights (kg): 73, 77, 84, 104, 109, 112, 113, 127, 136, 136, and 159. After deposition, TBS, photographs, and written qualitative descriptions concerning subject appearance and insect activity were collected daily. Accumulated Degree Days (ADD) were used to assess the thermal energy required for each subject to reach several TBS landmarks: early decomposition (TBS≥6.0); midpoint between early and advanced decomposition (TBS≥12.5); advanced decomposition (TBS≥19.0); halfway through advanced decomposition (TBS≥23.0); and skeletonization (TBS≥27.0).[7]

Preliminary statistical testing showed no significant positive or negative correlation between body weight and ADD at any TBS landmark. At TBS≥6.0, body weight accounted for 2.4% of the variation in ADD (r=0.155, p=0.65, n=11). At TBS≥12.5 (halfway through early decomposition), body weight explained 9.8% of the variation in ADD (r=0.296, p=0.377, n=11). At advanced decomposition (TBS≥19.0), 9.3% of variation in ADD was explained by body weight (r=0.305, p=0.36, n=11). Midway through advanced decomposition (TBS≥23.0), 4.1% of variation was explained by body weight (r=-0.202, p=0.55, n=11). At advanced decomposition (TBS≥27.0), 26.6% of the variation in ADD was explained by body weight (r=-0.516, p=0.29, n=6). Results suggested there is only a minor influence of body weight on the rate of outdoor decomposition in southern Illinois. Although not statistically significant, the correlation between body weight and ADD was positive until midway through advanced decomposition when this relationship became negative: larger-sized individuals required fewer ADD than smaller subjects to reach TBS≥23.0 and TBS≥27.0. The study's hypothesis was not supported by the results: there was no statistically significant correlation between decomposition rate and body size during any stage of decomposition.

In conclusion, results of this preliminary study suggest body weight is not a significant factor in driving human decomposition nor should it significantly impact PMI estimation. Additionally, it should be noted 2.4%-26.6% of variation in decomposition rate was explained by body weight depending on the stage of decomposition. Further research is necessary and ongoing.

A21 A Methodology in Differentiating Between Knives From Cut Marks on Bone

Melodi Ghui, Liverpool John Moores University, Byrom Street, Liverpool, AE L3 3AF, UNITED KINGDOM; Constantine Eliopoulos, PhD, Liverpool John Moores Univ, School of Nat Science & Psych, James Parsons Bldg, Byrom Street, Liverpool L3 3AF, UNITED KINGDOM; and Matteo Borrini, PhD, Liverpool John Moores University, RCEAP-School of Natural Science & Psych, Byrom Street, Liverpool L3 3AF, UNITED KINGDOM*

The goal of this presentation is to propose a flowchart as an additional tool to enhance the assessment of cut marks on bones.

This presentation will impact the forensic science community by offering a new implement to recognize characteristics of cut marks and provide an effective method to correctly identify the type of knife used.

Many studies in sharp force trauma discuss knife cut mark analysis in the context of dismemberment in murder cases; however, blunt force trauma and sharp force wounds are the most common injuries in crime, especially in homicides.[1] Furthermore, sharp force trauma has been debated as being the leading cause of murder in the United Kingdom.[2] The research in lesion identification on bones has been successful, particularly in determining the type of blade used (serrated or non-serrated); however, there has been no uniformity in the characteristics used to identify the weapon's type.[3,4]

This study was conducted with the goal of creating a standard method for knife identification based on specific characteristics detectable in the marks left on bone tissues. This study chose, as a starting model, the characteristics used for sword and saw cut marks analysis, adapting them to the study of knife injuries and specific characteristics (e.g., grooves).[5,6]

In this study, a total of 150 cut marks were made on domestic pig (*Sus scrofa*) rib bones. These bones were macerated to ensure complete removal of tissue before beginning the experiment. Three different categories of blade were used to inflict cuts on the surface of the bones: non-serrated; micro-serrated (eight Teeth Per Inch with, average distance between teeth: 3mm); and, macro-serrated (five Teeth Per Inch with, average distance between teeth: 4.9mm). During the experiment, the knife was moved one time forward and backward to simulate a stabbing action.

After microscopic analysis (10x7-10x45), χ^2 tests of independence were performed for all characteristics to determine the relation between trait and type of knife. According to the probability of correct identification of knife type by each characteristic, a flowchart was developed. The features were structured from the distinction between serrated and non-serrated, and then between micro- and macro-serrated blades. Four characteristics were chosen for the differentiation between serrated and non-serrated knifes: grooves along the kerf wall; flaking; kerf shape; and general aspect. An additional feature, the presence of shards, is used for the separation between micro- and macro-serrated blades.

A blind test on an additional 100 cut marks was performed. The accuracy of the identification with the support of the flowchart is very high (95%) in the diagnosis between non-serrated and serrated knifes; however, there is a difference when the kind of serration is analyzed as well (0.7%). This suggests that the flowchart needs further improvement in this area, with additional features for the distinction between micro- and macro-serrated blades.

To test how intuitive the use of the proposed flowchart is and the characteristics used, two groups of forensic anthropology students (five undergraduates and five postgraduates) were tested. None of them had received training on cut marks, but they had different degrees of experience in human anatomy and osteology. All undergraduates had significant differences when compared to more experienced individuals, while the results of the postgraduate students closer to the expected values. This result demonstrates that, even if an in-depth knowledge and training in osteology is a prerequisite, the proposed flowchart is a useful tool that has the potential to increase the reliability of knife cut mark analysis. In addition, its use appears to be intuitive and supports the possibility of introducing this method as a teaching tool in graduate programs.

Cut Marks, Forensics, Flowchart

A22 Traumatic and Congenital Anomalies of the Atlas: A Forensic Identification Case Report

Yann Delannoy, MD, Forensic Taphonomy Unit, Rue André Verhaeghe, Lille 59000, FRANCE; Thomas Colard, DDS, PhD, Institut de Médecine Légale, Place de Verdun, Lille, Nord 59045, FRANCE; Tania Delabarde, PhD, Institut Médico-légal, 2 place Mazas, Paris 75012, FRANCE; Jocelyn Pollard, MD, Place De Verdun, Lille 59045, FRANCE; Valéry C. Hedouin, MD, PhD, Iml-chu Lille, Rue Andre Verraeghe, Lille 59000, FRANCE; and Didier Gosset, MD, PhD, Institut de Medecine Legale, Faculte de Medecine, Lille 59045, FRANCE*

After attending this presentation, attendees will recognize which traumatic and congenital abnormalities of the craniovertebral junction can be used to identify skeletal remains.

This presentation will impact the forensic science community by providing information on the various existing traumatic and congenital anomalies of the cervical atlas. These rare abnormalities provide important data that could lead to a positive identification, such as in this case report.[1]

A partially skeletonized and unidentified body was discovered during the winter in northern France, hidden by vegetation and partially submerged in a swampy area. The identification card found in his clothes corresponded to a 48-year-old man. The victim had an old psychiatric illness and escaped from the hospital during the previous summer. Despite searches conducted by the police, he was never found.

Anthropological analysis revealed that the victim was an adult male, 170cm to 180cm in height, and 36 years to 54 years of age, which was compatible with the presumed identity. A callus was observed on the left clavicle and the examination of the cervical spine showed an old fracture of the atlas with two disjointed zones: one on the anterior arch and another on the posterior arch of the vertebra. Bone margins showed osseous changes associated with skeletal healing processes and remodeling (a Computed Tomography (CT) scan was performed in order to document this injury). The medical records of the victim mentioned an old fracture of the distal end of the left clavicle in 2006, compatible with the postmortem findings, without any other traumatic injury. Given the specific psychiatric history (schizophrenia and chronic alcoholism), several CT brain scans were performed during his hospitalizations and their analyses confirmed the atlas condition: a bursting fracture called the Jefferson fracture. This old fracture was never treated surgically and was never reported in the medical record (there was no sign of neck injury in the decedent's medical past). These bifocal fractures are rare and should not be confused with congenital abnormalities of the craniovertebral junction.

Unlike other cervical vertebrae that develop embryologically from three ossification nuclei (one in the vertebral body and one in each lateral mass), the atlas grows from two lateral ossification centers.[2] Around the seventh week of intrauterine life, ossification begins and extends dorsally. During the second year of life, a separate ossification center appears from the posterior tubercule of the atlas and these posterior arches fuse between three and four years of age. For the anterior arch, one or more ossification centers could appear during the first year of life, but it is possible that no ossification center arises; in that case, the anterior arch is formed from the lateral masses. The fusion is complete between six and eight years of age.[3] Because arches fuse anteriorly and posteriorly progressively, hypoplasia or aplasia might occur on the arches, as well as fusion anomalies (rachischisis or clefts). A rachischisis is possible for the anterior or posterior arches, and the "split atlas" is a fusion anomaly of both anterior and posterior arches. It is therefore important to recognize a split atlas as these osseous gaps may mimic a Jefferson fracture.

The Jefferson fracture results from an axial compressive force applied to the vertex with the neck held rigidly erect.[3] These arch fractures usually occur near the lateral masses (as in this case) and are difficult to observe on conventional radiographs. A CT scan is therefore essential for diagnosis.

Numerous congenital anomalies of the atlas vertebra exist. They must be known to the pathologists and anthropologists to differentiate them from fractures, because many fractures in this area are treated conservatively: Jefferson fractures are typically treated by a hard collar immobilization, provided that the transverse atlantal ligament is considered intact.[2-4] Furthermore, their rarity in the population can be a key element in identifying skeletal remains.

Positive Identification, Cervical Atlas, Congenital

A23 Comparison Between Peri-Mortem Blunt Force Trauma Identified in Bone During an Autopsy and During an Anthropological Examination of 21 Skeletonized Remains Several Years After Death

Luisa Marinho, MSc, Simon Fraser University, Dept of Archaeology, 8888 University Drive, Burnaby, BC V5A1S6, CANADA; and Hugo Cardoso, PhD, Simon Fraser University, Dept of Archaeology, 8888 University Drive, Burnaby, BC V5A 1S6, CANADA*

After attending this presentation, attendees will understand how an anthropological examination of skeletonized human remains can differ from an autopsy of a fresh cadaver in the identification of peri-mortem blunt force trauma to bone and what the specific circumstances of each examination are that can potentially explain any discrepancies.

This presentation will impact the forensic science community by increasing awareness about the limitations of both the autopsy and the anthropological examination, particularly in cases in which blunt force trauma is involved. Data generated from this comparison will emphasize the importance of a detailed investigation of skeletal trauma during an autopsy, as well as the influence of taphonomic factors that affect the preservation of skeletal material, as these have a negative impact on a thorough identification and subsequent interpretation of trauma mechanisms.

In this study, the number and location of peri-mortem fractures identified during the autopsy of 21 fresh cadavers were compared to the number and location of peri-mortem fractures identified during an anthropological examination of the same individuals several decades after death. These 21 individuals were selected from the identified skeletal reference collection housed at the National Museum of Natural History and Science (NMNHS, *n*=20), in Lisbon, Portugal, and the Collection of Identified Skeletons curated at the Life Sciences Department, University of Coimbra (CEI-UC, *n*=1), Portugal. These individuals are of known cause of death and were selected on the basis of a reported violent death associated with a blunt force mechanism. The autopsy reports generated for these individuals were examined at the archives at the National Institute of Legal Medicine and Forensic Sciences, in the Southern (Lisbon) and Centre (Coimbra) Delegations. Violent deaths due to other trauma mechanisms, such as gunshot wounds or sharp trauma, were not considered. Only 1 of the 21 cases analyzed had perfect correspondence between the number and location of peri-mortem fractures identified during the anthropological examination and the autopsy. A few cases had minor inconsistencies, while the majority of the individuals showed several more significant discrepancies.

This research explores the reasons that may explain these discrepancies and highlights the fact that fractures resulting from a blunt force mechanism are particularly susceptible to misidentification. If, on one hand, the identification of peri-mortem fractures during an anthropological examination is heavily influenced by taphonomic processes, rendering them undetectable at worst or their interpretation dubious at best, then, on the other hand, fractures that do not contribute to the cause of death can be missed during the autopsy or only vaguely reported. This study also draws attention to the value of identified skeletal collections where cause and manner of death are known, as they are invaluable sources of information for the study of skeletal trauma.

Peri-Mortem Fractures, Autopsy, Taphonomy

A24 Reassessing Blunt Force Trauma to True Rib Heads Utilizing Tension-Compression Theory

Kelsey A. Carpenter, BS, Howell, MI 48843; Kena Ihle, BA*, 440 W 9th, #11, Erie, PA 16502; and Steven A. Symes, PhD, Mercyhurst University, 501 E 38th, Erie, PA 16546*

After attending this presentation, attendees will better understand the influence that biomechanical factors have on fracture propagation of blunt force trauma rib heads. This will be achieved by the explanation and analysis of tension and compression.

This presentation will impact the forensic science community by providing preliminary answers to the unanswered question of how rib heads react during blunt force impact. This investigative study will help both forensic anthropologists and pathologists begin to better interpret rib fractures when presented with an unknown scenario.

Rib trauma is commonly used as a last interpretative resort in cases where repetitive trauma is present. This may largely be due to the complicated nature of rib anatomy and physiology complicating individual rib trauma analyses. There appears to be a lack of understanding of ribs on a biomechanical level when mapping and interpreting incomplete and buckle fractures from males and females of various ages.[1] An additional rib study reported that age and sex have little effect on blunt force fractures, suggesting that the study of geometric properties of ribs is imperative for further understanding of blunt force rib fractures.[2]

Introductory research investigating rib cortical area, section modulus, linear structural stiffness, and skeletal robusticity found the expected, in that robust bones are more resistant to bending and therefore more structurally sound when force is applied.[3] While the aforementioned study has taken steps in understanding the biomechanical properties of rib fractures, rib head, neck, and tubercle biomechanical studies have yet to be examined specifically and in terms of tension and compression. It is felt that the complex anatomical positioning of rib heads, accompanied by their robust nature, must reveal a significant diagnostic biomechanical pattern of blunt force fracture propagation in the thoracic region.

In this pilot study, ten rib head, neck, and tubercle fractures from five individuals were used. Only true thoracic ribs (ribs four through eight) from males and females with reported blunt force trauma to the chest were used for this study. The sample consists entirely of individuals examined by a member of this study. Scenarios for age at death and cause of death of each individual were previously recorded. Each fracture was analyzed macroscopically using a Leica® MZ16A microscope with 3.5x to 40x magnification capability. Tension and compression were identified on all fracture surfaces during analysis to assess the forces and behavior of the bone as it fractured.

Analysis of the ten ribs heads revealed consistent anatomical fracture patterns. Of the rib heads analyzed, 90% exhibited fractures originating medial to the rib angle, continuing around the tubercle, and propagating into the rib head. The remaining 10% of rib heads analyzed displayed only a hairline fracture between the head articular facet and tubercle, suggesting the blunt force impact was not great enough to fully radiate the fracture. The preliminary research has discovered that rib head fractures avoid more dense cortical bone (stress resistors), like that found at the tubercle, in all scenarios. The behavior of the fractures observed in this study is a result of the anatomical structure of the rib, including the immovable attachments to the vertebrae body and transverse process. The surrounding musculoskeletal and cartilaginous tissues also absorb the impact energy.

In conclusion, this research delves into the examination of blunt force rib head, neck, and tubercle fractures in an effort to better understand how ribs, as individual bones and as a unit, react to force. The ultimate goal of this study is to introduce effective means of interpreting blunt force trauma of the ribs by diagnosing tension and compression in each fracture. The increased accuracy of trauma analysis through biomechanically recognized bone bending can only contribute to an accurate understanding of bone bending and failure.

Biomechanics, Blunt Force, Ribs

A25 Comparability of Macroscopic, Microscopic, and Radiologically Defined Pediatric Antemortem Healing Stages

Cliff Boyd, PhD, Radford University, Dept of Anthropological Science, Radford, VA 24142; Donna C. Boyd, PhD, Radford University, Forensic Science Institute, PO Box 6939, Radford, VA 24142; Sharon Roller, 56 Harrison Avenue, Waldwick, NJ 07463; and David Foley, BS, Radford University, Dept of Anthropological Sciences, Radford, VA 24142*

The goal of this presentation is to compare macroscopically, microscopically, and radiologically based standards for assessing and interpreting pediatric antemortem fracture healing.

This presentation will impact the forensic science community by providing forensic anthropologists and pathologists with an understanding of the accuracy and potential problems associated with antemortem pediatric fracture interpretation based on different media and contexts. This research will demonstrate that there is considerable variation in observation of macroscopically, microscopically, and radiographically defined healing stages. Recognition of this variation will ultimately aid in more accurate identification of pediatric antemortem fractures in a forensic setting and lead to more precise determinations of time since injury for these fractures.

Recognition and dating of antemortem pediatric fractures in a medical examiner setting may first occur with the use of radiography, followed, in some cases, by macroscopic (gross), microscopic, and histological observation. Radiographic standards for antemortem pediatric bone healing have been derived from observation of immobilized fractures (of a usually accidental origin) in a clinical non-forensic context restricted in temporal extent. In contrast, macroscopic antemortem fractures observed in a forensic context may not have undergone immobilization and are often attributable to a non-accidental etiology. Temporal range of these fractures (e.g., time since injury) may be much broader.

In this study, more than 700 digital macroscopic, microscopic, and radiographic (both digital and analog) images depicting antemortem healing from 55 fractures originating from seven known forensic pediatric death (child abuse) cases are evaluated for the presence of diagnostic characteristics typically observed in bone healing. These characteristics include, but are not limited to, the presence of localized inflammation, rounding of fracture margins, subperiosteal new bone formation, organization of callus, hard callus formation, presence of distinct fracture lines, and resorption of fracture lines. These bone healing signatures are evaluated in relation to established macroscopic, microscopic, and radiographic standards for antemortem fracture healing and the total number of features observed in each medium compared across groups.[1-3]

Results of this study indicate limitations in radiographic-based identification and interpretation of antemortem fractures. This is especially characteristic of the diagnosis of very recent fractures, as well as aged fractures in late stages of remodeling. Identification of subperiosteal new bone formation, distinct fracture lines (particularly in the rib cage), and metaphyseal fractures are often occult in radiographic images. The highest percentage of identified indicators of the healing process through radiography occurred within the middle reparative stages due to the presence of callus formation. While macroscopic imaging allows greater observation of antemortem healing characteristics compared to radiography (particularly in the early and later stages), microscopic imaging reveals an increased number of clear healing features and holds the greatest promise for dating of these fractures.

These results indicate the following: (1) use of established standards for pediatric antemortem fracture identification, interpretation, and dating are heavily dependent upon the medium used (gross observation, microscopy, radiology) to define the stages; (2) specific standards should be developed for the appropriate medium used to assess and date antemortem fractures; (3) reliance on radiography for identification and interpretation of antemortem pediatric fractures is problematic and those standards developed in clinical settings may not be comparable to forensic ones; and, (4) microscopic imaging of the antemortem healing process is strongly recommended in cases of suspected child abuse.

Pediatric, Antemortem, Healing

A26 A New Statistical Approach to Morphological Sexing of South African Remains

Samuel R. Rennie, BSc, Liverpool John Moores University, Rm 439a James Parsons Bldg, Byrom Street, Liverpool L3 3AF, UNITED KINGDOM; Margaret Clegg, PhD, University College London, Gower Street, London WC1E 6BT, UNITED KINGDOM; and Silvia Gonzalez, PhD, Liverpool John Moores University, Byrom Street, Liverpool, Merseyside L3 3AF, UNITED KINGDOM*

After attending this presentation, attendees will better understand the Summary Sex methodology and how it can be used to assess human remains regardless of population affinity.

This presentation will impact the forensic science community by demonstrating how using the population-specific equations and a universal South African equation makes it possible to estimate sex with a high degree of accuracy.

Anthropologists agree that the most sexually dimorphic element in the human skeleton is the pelvis. This can be explained by the strong selection pressure for bipedality and childbirth; however, when sexing the pelvis, different morphological features can display conflicting results when analyzed separately, so an overall assessment of multiple indicators is generally best. Sadly, in many forensic and archaeological cases, complete remains are rare, and forensic specialists normally have to attempt estimating a biological profile using fragmented remains.

Summary Sex is a multivariate approach to sex estimation that uses a Principal Components Analysis (PCA). This is achieved by analyzing ordinal data collected from up to nine morphological features on the human pelvis. Each of the morphological traits are scored between -2 (hyper-feminine) and +2 (hyper-masculine) with 0 being an ambiguous score. First, only complete remains are analyzed, and a linear equation is created from the first Principal Component (PC). Second, if a specimen is missing any data, the median value for that specimen is calculated and replaces all missing scores. For example, the specimen has five of the nine morphological features present which have the scores of -2, -1, -2, 0, -1, then the remaining four missing scores would have the value of -1. The median was chosen to replace missing values as it follows the amount of sexual dimorphism that is seen in the pelvis and doesn't create a "muddying" effect when plotted.

Two South African samples were created using the modern-day skeletal collections of the Pretoria Bone Collection (housed at the University of Pretoria) and the Raymond Dart Collection (housed at the University of the Witwatersrand). As these are cadaver-based collections, age, sex, and ancestry are known for each individual. South African Whites (*N*=193) and Blacks (*N*=204) were analyzed separately to create specific equations for each group. From this, comparisons were made between the two equations and were tested against each other to assess the possibility of different percentage accuracies. A second analysis was performed which pooled the two samples together to form an overall South African sample (*N*=397) to create a new equation which was compared against the equations created from the population-specific equations.

The Summary Sex equation for the specific groups resulted in 94.82% accuracy for South African Whites and 89.95% for South African Blacks. When comparing results, the South African White equation on the South African Black data resulted in 89.48% accuracy and the South African Black equation on South African White data was 94.82%. When pooling both groups, correct classification of sex was 92.70%. When this overall equation was then applied to only Black or White South Africans, it resulted in accuracies of 89.95% and 94.82%, respectively.

What this methodology shows is that, unlike Discriminant Function Analysis where knowledge is needed *a priori*, a PCA approach has the ability to classify males and females with high accuracy. Also, Summary Sex allows a researcher to observe the range of sexual dimorphism present within a given population. Furthermore, Summary Sex shows the capability of analyzing specimens that are fragmented and still retain a high percentage of accuracy.

Principal Components Analysis, Pelvis, Forensic Anthropology

A27 Estimating Ancestry in South Africa: A Comparison of Geometric Morphometrics and Traditional Craniometrics

Rebecca King, MS, 7710-T Cherry Park Drive, #383, Houston, TX 77095; Jonathan D. Bethard, PhD, Boston University School of Medicine, Dept of Anatomy & Neurobiology, 72 E Concord Street, L1004, Boston, MA 02118; and Donald F. Siwek, PhD, Dept Anatomy and Neurobiology, Program in Forensic Anthropology, 72 E Concord Street, Boston, MA 02118*

After attending this presentation, attendees will better understand: (1) the accuracy of two ancestry estimation software programs, FORDISC® 3.1. and 3D-ID, using discriminant function analysis in an international population; (2) which of these programs performed more accurately in the South African Black and White populations respectively; and, (3) suggestions for the improvement of these programs to make them more readily useful in contexts outside of the United States.

This presentation will impact the forensic science community by revealing accurate methods of estimating ancestry in South African individuals and distinguishing between Black and White individuals in the population. This presentation will encourage a broader scope in the utilization of ancestry estimation software programs created in the United States as forensic contexts abroad become more relevant.

In ancestry estimation of South African individuals, non-metric morphological trait assessment has not proven useful and previous results using FORDISC® leave room for improvement.[1,2] Results, when compared against the Forensic Databank (FDB) of FORDISC® 3.0 and a custom-made South African Database (SADB), both linger below the universally accepted accuracy of 75% for use in a forensic context.[2]

The accuracy rates of software programs FORDISC® 3.1 and 3D-ID were compared for ancestry estimation based on cranial data of Black and White South Africans using discriminant function analysis. Cranial landmarks were digitized using a MicroScribe® G2 for geometric morphometric analysis in 3D-ID, and traditional craniometric measurements for use in FORDISC® were calculated from these points using the data collection software 3Skull. Data was collected from a total of 385 individuals (186 Black and 199 White crania) from the Pretoria Bone Collection, University of Pretoria, South Africa. Overall accuracy rates of 75.6% using FORDISC® 3.1 and 63.1% using 3D-ID were obtained for Black and White South Africans. An assessment of intra-observer error was performed using intra-class correlation coefficients and all data showed high correlation between separate measurements of the same individual. Previous studies of inter-observer error in the use of a MicroScribe® to obtain cranial data showed agreement between Type I and Type II landmarks, with some dissent when collecting Type III landmarks.[3]

Higher accuracy rates were obtained when sex of the individual was already known or sex estimates made by the programs were disregarded. Incorrect estimates were more often due to misclassifications of sex rather than ancestry, reflecting the decreased amount of sexual dimorphism in South African populations when compared against American populations, discussed previously.[2] Black South Africans were more often classified correctly in FORDISC® 3.1, and White South Africans were more often classified correctly in 3D-ID, showing opposing biases in the two programs.

Low sample size in comparative databases and broad ancestral differences between South Africans and the proxy populations used, which included American, European, and African, likely explain the low accuracy rates. The accuracy rates obtained in FORDISC® 3.1 are slightly above 75%, making the program acceptable for use in a forensic context to estimate the ancestry of Black and White individuals in South Africa. 3D-ID has performed poorly in this population, though in some cases the program estimated ancestry correctly when FORDISC® 3.1 estimated the ancestry of the same individual incorrectly. Though FORSDISC® performed more accurately than 3D-ID, the use of both programs in conjunction can help South African anthropologists in estimating ancestry and ensuring correct classifications.

Ancestry, FORDISC®, 3D-ID

A28 Spatial Analysis on a Global Scale: Cranial Non-Metric Trait Variability

Joseph T. Hefner, PhD, Michigan State University, Department of Anthropology, 355 Baker Hall, East Lansing, MI 48824; and Caitlin C.M. Vogelsberg, MS, Michigan State University, Dept of Anthropology, 354 Baker Hall, East Lansing, MI 48824*

After attending this presentation, attendees will understand some principles of cranial non-metric trait analysis with geospatial tools, the necessary elements for the application of geospatial analysis in biodistance studies, and an example of the practical application of geospatial analysis.

This presentation will impact the forensic science community by quantifying global variation in cranial non-metric traits through novel geospatial tools that permit the visualization of qualitative variables.

Cranial non-metric trait (*sensu stricto*) variation in ancestry estimation has been documented by multiple researchers, but the global distribution of that variation using geospatial analyses and large samples has not been explored. Using a dataset of nearly 8,000 individuals, this study explored global spatial variation and the underlying patterns of trait distributions in an effort to fine-tune the analysis of cranial non-metric traits in the estimation of ancestry. Prior to analysis, a selection of Ossenberg's database (n=4,579) was appended to include centroid data (decimal degrees) for each individual from each World Region, each Major Region (by country), and each Country Region (by specific region). To explore how cranial non-metric traits vary around the world and to determine which traits are more useful for population estimations, Ossenberg's dataset was subjected to Principal Components Analysis (PCA) and Principal Coordinates Analysis (PCO) using the generalized inverse of each variable. These data were analyzed within a geospatial framework modified for biodistance analysis.

Experimental variograms explore the relationship between a biological distance measure and the physical (spatial) distance between individuals while providing empirical information regarding the magnitude, extent, and pattern of spatial correlation. The pattern of the variogram suggests the level of spatial autocorrelation. For example, an undulating variogram indicates a correlation between physical distance and biological distance. Following variogram analysis, this study used the calculated spatial correlation to interpolate values between individuals and the empty space between them to construct a smooth plot from contour data using a kriging method. Kriging is a regression method used to estimate unsampled values using a weighted average of known values from nearby individuals. Unlike ad hoc methods, kriging is weighted using the specific underlying pattern of spatial correlation and variation derived from the variogram analysis. The result is a map highlighting the relationship between the individuals or populations. Levels of global spatial autocorrelation were measured using Moran's I, which tests the probability that the amount of spatial clustering present is not due to random chance. Moran's I ranges from 1 to -1, where I >1 indicates a statistically significant positive autocorrelation and I <1 a negative autocorrelation. Additionally, a minimally variable z-score is computed following random permutation calculations (N_p=199 for this analysis). This score also indicates statistical significance for positive autocorrelation when z >1.96.

Following PCA, the factor loadings were examined to determine trait clustering. The first PC explained nearly 40% of the sample variation. The highest loadings for this PC all centered on the highly canalized structures of the basicranium, particularly in the basiocciptal region (e.g., the highest loadings for the first PC were transverse fissue of basiocciput, odonto-occipital articulation, precondylar tubercles). In direct contrast, the second PC, which accounted for an additional 12% of the variation, predominately loaded cranial non-metric traits of the mandible, demonstrating a shift in importance to the lower face. The results of this spatial analysis may explain this shift. These results indicate positive spatial autocorrelation for each of the first four PCs. The Moran's I for the four principal components were, respectively, I=0.07163 (z=~45), I=0.122443 (z=~81), I=0.294553 (z=~190), and I=0.06075 (z=~40). These values indicate that although the second PC explained less of the variation in the sample, it has more spatial dependence (clustering) than the first, while the third PC has the highest level of clustering of these four. Visualization of these clusters sheds light on their patterns of variation and how they shift across space.

This research supports the applicability of cranial non-metric traits in the estimation of ancestry, beyond merely supplemental notes collected during more "trusted" metric or macromorphoscopic analyses. Geographic spatial clustering of grouped cranial traits is evident and, therefore, these traits should be investigated when attempting to assess the ancestry of unknown human remains.

A29 Examining Inter-Observer Reliability of Metric and Morphoscopic Characteristics of the Mandible

Jennifer F. Byrnes, PhD, University of Hawaii - West O'ahu, 91-1001 Farrington Highway, Kapolei, HI 96707; Michael W. Kenyhercz, PhD, University of Tennessee, 250 S Stadium Hall, Knoxville, TN 37996; Samantha C. Torres, BA, University of Hawai'i - West O'ahu, Div of Social Sciences, 91-1001 Farrington Highway, Kapolei, HI 96707; and Gregory E. Berg, PhD, DPAA Identification Laboratory, 310 Worchester Avenue, Joint Base Pearl Harbor-Hickam, HI 96853-5530*

After attending this presentation, attendees will understand the reliability of metric and morphoscopic characteristics of the mandible for sex and ancestry estimation.

This presentation will impact the forensic science community by providing inter-observer tests of reliability using observers of varied experience levels for sex and ancestry estimation methods focused on the mandible.

To date, there has been no large study of the reliability of metric and morphoscopic traits of the mandible. Berg provided the forensic anthropology community with a method for the estimation of sex and ancestry using 6 morphoscopic and 11 metric characteristics of the mandible from various world populations.[1,2] A combination of morphoscopic and metric variables were shown to discriminate sex and ancestry best. Further, intra-observer error was shown to be low.

An inter-observer agreement study of the mandibular variables was conducted by four researchers with varied experience using the standard descriptions of metrics, as well as new metric descriptions and scoring criteria described by Berg.[1,2] The standard metric variables included GNI, HML, TML, GOG, CDL, WRB, XRH, MLT, MAN, and two new measurements, mandibular body breadth at the M2/M3 junction (TML23) and dental arcade width at the third molar (XDA). The morphoscopic traits included Chin Shape (CS), Lower Border of the Mandible (LBM), Ascending Ramus Shape (ARS), Gonial Angle Flare (GAF), Mandibular Torus (MT), and the Posterior Ramus Edge Inversion (PREI). The sample data were derived from the William M. Bass Donated Skeletal Collection at the University of Tennessee, Knoxville. In total, this study examined 183 mandibles (white females=66; White males=96; Black females=2; and Black males=19) from known individuals and an additional 189 mandibles (White females=91; White males=88; Black females=4; Black males=6) were also examined.

To test the agreement among observers, the Intra-Class Coefficient (ICC) was used. The ICC quantified the proportion of variance that was ascribed to observations. For reliability, both complete agreement and consistency were evaluated using a two-way, random model ICC with a 95% confidence interval. Additionally, for the metric variables, the Technical Error of Measurement (TEM) was calculated. Both ICC and TEM were calculated with four observers for one test and three experienced observers in a second test in order to examine the effect of experience on agreement.

The ICC for the morphological variables for four observers ranged from 0.37 (PREI) to 0.75 (MT). The ICC values for the three experienced observers ranged from 0.43 (LBM) to 0.74 (MT). The majority of morphoscopic ICC values were between 0.67 and 0.74 (three observers). Each of the ICC values was significant at $p < 0.001$. The ICC values for the metric variables for four observers ranged from 0.73 (TML23) to 0.98 (CDL). Experienced observers ranged from 0.80 (TML23) to 0.99 (WRB). The majority of metric ICC values were between 0.91 and 0.99, and all were significant at $p < 0.001$. The TEM of the metric variables ranged from 1.16mm or 1.00% TEM (CDL) to 1.62mm or 10.53% TEM (TML). The TEM for MAN was 2.19 degrees or 1.74% TEM.

The results show that each of the variables has significant correlation among observers, though the metric variables were more accurately replicated than the morphological traits. Experience plays a role for scoring and measuring the mandible. The most consistent error found in the metric data was measuring the mandibular angle, where the least experienced observer had 11 instances of being exactly 10 degrees different, indicating measurement reading errors.

The morphoscopic and metric variables are reliable and valid, though recognition of PREI is the most problematic. The morphoscopic traits had moderate agreement between observers, which is related to observer experience. The most variable metric trait between observers was TML (10.53% TEM), which may relate to problems when teeth obstruct a superiorly derived measurement. Overall, the metric measurements among observers have high agreement. In using the methodology presented by Berg, it is suggested that practitioners become sufficiently familiar with the trait definitions and scoring attributes as well as the range of variability in mandibular morphology.

Anthropology, Reliability, Error of Measurement

A30 Decision Trees and Non-Metric Traits: A More Accurate Approach for Sex Estimation of the Skull

Natalie R. Langley, PhD, Lincoln Memorial University, DeBusk College Osteopathic Med, 6965 Cumberland Gap Parkway, Harrogate, TN 37752; Alesia Cloutier, MS, Lincoln Memorial University, DeBusk College Osteopathic Med, 6965 Cumberland Gap Parkway, Harrogate, TN 37752; Cade Lampley, MS, Lincoln Memorial University, DeBusk College Osteopathic Med, 6965 Cumberland Gap Parkway, Harrogate, TN 37752; and Beatrix Dudzik, PhD, 250 S Stadium Hall, Knoxville, TN 37996*

After attending this presentation, attendees will gain an appreciation for the use of different combinations of non-metric traits of the skull and the utility of predictive decision trees. Combined, these approaches provide a more accurate and simpler method than has traditionally been used by anthropologists.

This presentation will impact the forensic science community by providing a modified scoring system and data manipulation approach that performs variable selection to achieve maximum accuracy with sex estimation. Decision trees are an attractive statistical approach as they can handle numeric and categorical data and do not require normal distributions. As the non-metric scoring systems so often implemented by anthropologists often encompass these parameters, this approach can be incredibly useful.

The use of non-metric categorical scoring methods to estimate sex in skeletal remains is frequently implemented by forensic anthropologists. Traits of the skull have long been a staple in building the biological profile and associated methods are almost always cited in official reports. The most commonly used method of determining sex from the skull is an ordinal scoring system developed by Walker.[1] Despite its widespread use by practitioners, validation studies have indicated that all traits are not equally useful in sex estimation.[2-4]

Low accuracy rates have been attributed to high variability, inadequate categories, and/or definitions for specific traits. Despite obvious flaws with the Walker traits, few proposals have offered a solution to improve the system. Using the decision tree approach allows for quantification of the predictive power of included variables and provides insight into which traditional non-metric traits may not be of value.

Six cranial traits were scored on 220 American skulls of European descent (n=110 males and 110 females) from the UT William M. Bass Donated Skeletal Collection. The traditional variables of the nuchal crest, mastoid process, supra-orbital margin, glabella, and mental eminence were implemented. Additionally, the zygomatic extension was also included, which is often absent in previous studies. Ordinal scores for each variable were partitioned into training and validation samples and decision trees were created using the Rattle graphical user interface available in R.[5,6]

Preliminary results indicate that high correct classification percentages can be reached with smaller subsets of variables. Glabella was one of the most important discriminatory variables, while the mental eminence showed little significance. This supports the results of recent, related publications. Correct classification percentages were reported at 89%-90% for the validation sample, even when using only one or two traits. Further analyses with larger sample sizes and the possible inclusion of newly defined traits will indicate ultimately what combination of variables can simultaneously maximize prediction and reduce user error. As it has been shown by many studies (including the current work) that the mental eminence shows high levels of variability and low predictive power for sex estimation, it is argued that the trait and scoring method should be redefined in such a way that accounts for the range of morphologies often seen between and among the sexes. Additionally, further expansion on the results reported in this study will include more samples that are representative of other ancestries and thus have more relevance for forensic contexts.

Sex Estimation, Non-Metric, Decision Trees

A31 Sex Assessment — The Utility of Endocranial Landmark Data

Sean Y. Carlson-Greer, BA, School of Medicine - University of Missouri, One Hospital Drive, Columbia, MO 65212; and Stephen D. Ousley, PhD, Dept of Anthropology/Archaeology, Mercyhurst University, 501 E 38th Street, Erie, PA 16546*

After attending this presentation, attendees will understand the potential applications of 3D digitized landmark data to sex assessment of endocranial skeletal remains, specifically, the creation, definition, and utilization of standardized endocranial landmarks and Interlandmark Distances (ILDs) that can be used to assess sex in cases of fragmentary cranial remains.

This presentation will impact the forensic science community by explaining how this analysis will increase the potential number of cranial measurements that can be taken from a set of remains, and allow for more confident assessments of sex in cases of incomplete or fragmentary materials.

Biological profile is a crucial part of any forensic anthropological investigation, of which sex is one influencing factor. Fragmentation and erosion of skeletal remains acts to complicate both metric and non-metric assessment of skeletal remains and lessen the number of potential measurements that can be taken; however, the cranium offers a unique skeletal structure in that fragmentation allows for direct access to complex surfaces and structures that increases the possible number of direct measurements.

Use and definition of ectocranial landmarks have a long history dating back more than a century. In general, these landmarks are now well defined, and their use in everyday craniometrics is standard practice. On the other hand, endocranial structures are rarely defined in terms of landmarks. When endocranial landmarks are identified, their definitions typically lack specificity and leave their exact location open to interpretation. This lack of specificity increases the potential of measurement error and incorrect assessment when data from different samples or studies are collated.

Over the past decade, researchers, including Isaza et al. and Kalmey and Rathbun, have begun to investigate metric sex differences of endocranial structures.[1,2] These studies have shown promise for the use of these structures for sex assessment, both using traditional caliper measurements and computer assisted ILDs; however, previous research has focused on isolated areas within the cranium, leaving out overall morphology or uses landmarks that are methodically difficult to locate and identify.

The present study examined 330 crania from the Rainer Osteological Collection in Bucharest, Romania. Nine midline and 11 bilateral landmarks were defined and collected from the crania using a MicroScribe® G2X digitizer. Landmarks were excluded on an individual basis in cases of fragmentation, erosion, or expression of diffuse or localized pathological conditions. ILDs were extracted for all possible landmark combinations, and subsets of regionally clustered landmarks were created to simulate potential areas of cranial fragmentation. Each set of ILDs was analyzed using discriminant function analysis.

Of the 465 possible interlandmark distances across the entirety of the endocranial surface, a subset of 11, selected in a stepwise analysis, rendered cross-validated classification accuracies up to 85% with an almost negligible observed sex-bias below 5%. Simulated fragmentary analysis of four regionally clustered sets of landmarks results in cross-validated classification accuracies of up to 75% with a sex-bias below 5%. While the classification accuracies reported here are lower than those reported for traditional ectocranial landmarks, they are still appropriate for reliable and statistically sound assessments, particularly of fragmentary materials. Unlike ectocranial landmarks, endocranial structures that are well suited for landmarks are unaffected by muscular attachments that can greatly increase sexual dimorphism of a region or of measurements. While the endocranium has been mostly ignored in terms of sex assessment, with the exception of the petrous portion, it is a complex 3D surface that has great potential in expanding the number and types of analyses that can be used for assessment of the biological profile.

Biological Profile, Sex Assessment, Endocranium

A32 Femoral Neck Axis Length (FNAL): Use in Sex and Ancestry Estimation of Hispanic Populations

Audrey Murchland, BS, 25 Perth Court, Springboro, OH 45066; Lori E. Baker, PhD, Baylor University, Forensic Research Lab, One Bear Place, #97173, Waco, TX 76798-7173; and Rebecca Meeusen, MS, 42531 Rockrose Square, Unit 302, Ashburn, VA 20148*

After attending this presentation, attendees will be familiar with the FNAL measurement as well as how FNAL can now be used to estimate sex from skeletal remains in Hispanic populations.

This presentation will impact the forensic science community by expanding the use of the FNAL method in sex determination for Hispanic populations. This method will facilitate the identification process for deceased immigrants of Hispanic ancestry on the United States southern border.

Since 1998, the bodies of more than 6,300 deceased undocumented immigrants have been discovered along the United States-Mexico border.1 The majority of these individuals are of Hispanic ancestry. Traditional sexing methods, using standards developed from skeletal collections of American Whites and American Blacks, do not accurately sex those of Hispanic ancestry. In fact, 53% of Hispanic males are misclassified as females using these standards.[2]

Recent studies examining FNAL defined the measurement as the distance from the base of the greater trochanter (the point directly inferior to the greatest lateral projection of the greater trochanter) to the apex of the femoral head, excluding any lipping on the fovea capitus femoris.[3,4] Meeusen measured the FNAL from skeletonized remains of American Black, American White, and Native American samples of both sexes and showed that the FNAL measurement classified ancestry with low accuracy rates, ranging from 41.6% to 48.5%, and classified sex with high accuracy rates, ranging from 84.5% to 87.0%.4

In this study, the FNAL measurement was examined to determine its potential use for sex and ancestry estimation of Hispanic populations. FNAL was measured on skeletally mature adults, void of visible anomalies potentially affecting the measurement. Data was collected from Undocumented Border Crosser (UBC) cases recovered from Falfurrias, TX, (*n*=58: F=21, M=37) by the Reuniting Families Project. These data were then compared with the data from Meeusen: 87 (F=32, M=55) American Black; 108 (F=54, M=54) American White; and 91 (F=44, M=47) Native American individuals.

Statistical analyses were conducted in SPSS and included one-way Analysis of Variance (ANOVA), stepwise Discriminant Function Analyses (DFA), cross-validated sectioning point classification rates, and Bayesian analyses. In addition, a random subset of 55 femora was measured in a second trial for the purpose of intra-observer error assessment. Results showed low intra-observer error, with a Technical Error of Measurement (TEM) of 0.32mm and a coefficient of Reliability (R) of 0.99. A random subset of nine femora was also measured in a second trial for the purpose of inter-observer error assessment. Results showed low inter-observer error, with a TEM of 0.53mm and a R of 0.99, confirming previous repeatability assessments of the measurement.

One-way ANOVA revealed significant differences in FNAL between ancestral groups, with American Whites having the largest FNAL, followed by American Blacks, UBCs, and then Native Americans. Post-hoc Tukey HSD comparisons showed that American White FNALs are not significantly different from American Black FNALs (P=0.881), and UBC FNALs are not significantly different from Native American FNALs (P=0.998). DFAs classified samples by ancestry poorly, with accuracy rates ranging from 34.7% to 40.4%.

One-way ANOVA results also showed significant differences in FNAL between sexes, with male FNALs being significantly larger than female FNALs (P <0.001). DFAs classified samples by sex well, with accuracy rates ranging from 83.4% (ancestry-pooled) to 91.4% (UBC only). The UBC sectioning point, calculated at 87.5mm, provides a classification accuracy of 90.5% for females and 89.2% males.

The FNAL measurement has not been previously applied to Hispanic populations for either sex or ancestry estimation. Using FNAL measured from skeletonized femora, the 87.5mm UBC sectioning point correctly predicts sex at a rate of ~90%. Due to the skeletal variability seen in UBCs and their unidentified status, this sample provides only preliminary information about Hispanic populations. Further collection and analysis of Hispanic skeletal remains is encouraged.

Femoral Neck Axis Length, Sex Determination, Hispanic

A33 A Multiple Classifier System Approach to Determining Ancestry of Fragmentary Remains: A Preliminary Study

Amber M. Plemons, BS, Mississippi State University, 206 Cobb Institute of Archaeology, Mississippi State, MS 39762; Nicholas P. Herrmann, PhD, Mississippi State University, Cobb Inst Archaeology, Box AR, Dept of Anthro & Mid East Cultures, Mississippi State, MS 39762; and Edward F. Harris, PhD, University of Tennessee, Memphis, Dept of Orthodontics, College of Dentistry, 875 Union Avenue, Memphis, TN 38163*

After attending this presentation, attendees will understand how to utilize a multiple classifier system to best estimate ancestry from human skeletal remains and to select the best-suited methods of ancestry estimation when analyzing fragmentary remains.

This presentation will impact the forensic science community by encouraging a holistic approach to determining ancestry by combining extensive theoretical and methodological research and data collection of previous researchers in attempts to increase reliability of ancestry estimations in the future.

The goal of this research was to assess the most commonly available indicators of ancestry in a fragmented skeletal collection and test a statistical framework for combining all available methods.

Various methods for determining ancestry have been explored, most notably cranial and postcranial metrics, cranial morphology, dental metrics, and dental nonmetric traits, yet little effort has been made to combine these methods for comprehensive ancestry estimation.[1] Furthermore, the current approaches are heavily dependent on complete or mostly complete skeletal remains. The most frequently used methods of ancestry estimation are cranial and postcranial metrics, which are classified via Discriminant Function Analysis (DFA) in the FORDISC® software. Such customized software packages allow for the input of partial datasets; however, these methods are rarely feasible when dealing with fragmentary remains.

This study focuses on combining dental metrics, dental non-metric traits, and cranial macromorphoscopic traits to assess the ancestry of 67 individuals from the Mississippi State Asylum (MSA) Cemetery in Jackson, MS. The asylum records divided the institutionalized population into two classifications of social race (White and Black) and, therefore, a binary classification was developed using European and African American reference datasets. Cranial and postcranial metrics were not used for this study due to the high degree of fragmentation and poor preservation. Individuals with no dentition represented were excluded as this only leaves cranial macromorphoscopic traits to be assessed, reducing the sample to 57 individuals. Dental metrics for each MSA individual were entered into FORDISC® 3.0 and referenced to a dataset of American Blacks and Whites from the University of Tennessee College of Dentistry, Memphis, TN, using the custom import feature in order to calculate posterior and typicality probabilities.[2] Posterior probabilities were then calculated for each individual using dental non-metric traits referenced to frequencies developed by Edgar.[3] Finally, cranial macromorphoscopic were assessed using seven traits established by Hefner.[4] All observed macromorphoscopic traits were incorporated into a Bayesian classifier to calculate posterior probabilities, but this method was limited due to fragmentation. The group of posterior probabilities from the dental metrics, dental non-metric traits, and macromorphoscopics was then averaged, where each classifier was weighted equally.

When comparing the ancestry classifications across methods, 38 of the 57 individuals (66.67%) had consistent classifications. Of the 38 individuals with consistent ancestries, 84.21% had average posterior probabilities greater than 0.75. While there does not appear to be any significant correlations between the consistency of classification across methods and the number traits or metrics used, there is a strong positive correlation between the number of dental non-metric traits used and the posterior probability (r=0.43, p=0.0008). The limited sample size for macromorphoscopic traits rendered correlation tests insignificant; however, it should be noted that the combination of characteristics likely determines accuracy of the methods rather than quantity of metrics and non-metric traits. A discussion will be provided on the availability of each characteristic used to classify the fragmentary remains and trends in combinations of variables, as well as their correlations, within each classifier for all cases of consistent classifications. Additionally, the utilization and issues encountered when dealing with cranial macromorphoscopic traits will be presented.

Jantz and Hefner recommend that researchers embrace the theory of forensic race estimation by providing empirical data engrained with concepts of human variation.[5] This study is an example of such research targeted at creating appropriate and reliable statistical methods for determining ancestry of unidentified remains, as well as an aid in improving the establishment of biological profiles of fragmentary remains.

Ancestry, Fragmentary Remains, Multiple Classifier Systems

A34 Widening the Scope and Expanding the Field: An Argument for Sociocultural Anthropology's Seat at the Table

Sarah Wagner, George Washington University, Dept of Anthropology, 2110 G Street, NW, Washington, DC 20052*

After attending this presentation, attendees will understand how sociocultural anthropological studies of forensic science, particularly forensic anthropology applied in contexts of ongoing violence and post-conflict communities, elucidates the co-constituting relationship between science and society.

This presentation will impact the forensic science community by fostering dialogue among members of its subdisciplines, especially physical and sociocultural anthropology, about the general field and its theoretical momentum concerning issues pertinent to the recovery and postmortem identification of missing/unknown persons.

Taking forensic anthropological investigations into human rights abuses and missing persons populations as the point of departure, this presentation argues for a more nuanced, theoretically informed understanding of how forensic science is executed and how its results affect lives and communities.[1] In doing so, this presentation builds on two conversations already begun within the Anthropology Section of the American Academy of Forensic Sciences (AAFS): the 2014 decision to change the section name from "Physical Anthropology" to "Anthropology," in which members acknowledged that sociocultural anthropologists were actively contributing to the general field through ethnographic analyses of forensic work; and the set of presentations on "Theory in Forensic Anthropology" delivered at the 2015 AAFS Annual Scientific Meeting. These initial discussions underscored the importance of considering the scope and application of forensic anthropology and which theoretical questions underpin its work.

This presentation goes further, asserting the basic premise that science is never apolitical; rather, it is situated within a specific sociohistorical context and bound up in co-productive relations of political will, social values, cultural practice, and economic conditions.[2] Two examples support this claim. The first is drawn from the forensic efforts to identify the 30,000 missing persons from Bosnia and Herzegovina, specifically the more than 8,000 Bosnian Muslim (Bosniak) men and boys missing as a result of the Srebrenica genocide, where scientific success has yet to translate into enduring sociopolitical repair, despite the goals of its international sponsors.[3] In the Srebrenica case, tensions between individual (and individuated) identity and collective ethnonational identity are often exacerbated during the annual mass burial of identified victims in the communal cemetery of the Srebrenica-Potočari Memorial. Data culled from 12 years of ethnographic analysis of the identification efforts and its results, including the 20th anniversary of the genocide, July 11, 2015, document this tension.

The second example is of the United States military's decades-long efforts to account for its service members listed as Missing In Action (MIA) and presumed dead from the major conflicts of the past century. Recent attempts at reorganizing the government agencies tasked with MIA accounting make manifest the politics of national commemoration influencing not only the inner workings of forensic science but also how these results are perceived by the wider public.[4] Debates surrounding externally dictated quotas for annual identifications, acceptable margins of error, and the role of forensic anthropology in the scientific process expose the politics of a cost-efficient model of MIA accounting.

In examining the co-productive relations between science and society (postwar Bosnia and Herzegovina and contemporary United States), this presentation demonstrates that forensic anthropological efforts to document human rights abuses and/or recover and identify missing or unknown persons cannot be separated — analytically or practically — from the sociopolitical and economic conditions in which they unfold. In failing to recognize the contingent nature of knowledge production, scientists, policy makers, and the wider public risk overlooking, in particular, the political consequences of these forensic efforts.

Sociocultural Anthropology, Missing Persons, Politics

A35 The Social Process of a Forensic Identification

Hugh H. Tuller, MA, Defense POW/MIA Accounting Agency, 310 Worchester Avenue, Joint Base Pearl Harbor-Hickam, HI 96853-5530*

After attending this presentation, attendees will have a fuller understanding and appreciation of how the social interactions between scientific and non-scientific actors can shape the forensic identification process.

This presentation will impact the forensic science community by exploring the nature of objective scientific practice in human identification through the lens of Science and Technology Studies, which theorizes that much of scientific work is far from neutral, value-free observation. Understanding this nature will better prepare the field of forensic anthropology to mitigate effects of bias and lead to more comprehensive identifications.

This presentation seeks to expand the conversation on theory in forensic anthropology introduced during last year's AAFS Annual Scientific Meeting. In particular, this presentation will engage with Winburn's analysis of knowledge production within the field, further interrogating the view that positivist science is value-free and separate from the social context in which it is produced.[1] Rather, this presentation argues that the scientific process of identification itself is a cultural artifact. As such, its results represent a truth accepted as a "black box" — the inner workings of which are known to be complex, but that complexity is not necessary to understand.[2] In reality, the process is not only scientifically sophisticated, but also profoundly affected by social interaction and subjectivity where discrepancies and potential bias are ignored or downplayed.

As an example of Winburn's critique, this presentation will demonstrate how the forensic identifications produced at the Defense POW/MIA Accounting Agency's Central Identification Laboratory (DPAA-CIL) are based on amalgamations of decisions and interpretations scientists make in the course of their examinations and tests, the interactions they have with their scientific peers, supervisors, and non-scientists, as well as the influences of historical, political, and economic factors. These interactions are partly the nature of the work that requires interactions with outside laboratory actors and partly built into the protocols and standard operating procedures of the institution. Together, they form a particular DPAA-CIL cultural viewpoint and an approach to the work that often goes unexamined and unchallenged.

The process of a forensic identification and indeed the production of scientific knowledge are usually perceived as a neutral truth-finding practice that discovers facts through the unbiased testing of hypotheses or application of proven methods and techniques. This process is viewed and even trumpeted as one devoid of social influence, where the production center of knowledge is like a citadel whose walls prevent biased influences from the rest of the world.[3] In this manner, science is seen as cultureless by both the lay public and scientists themselves.[4] Embracing this view, most forensic anthropologists involved in the identification of an unknown individual subscribe to the belief that a positive identification is the result of sterile, neutral, stand-alone science; however, as the example of DPAA-CIL reveals, an identification involves the review by the CIL's Scientific Director of a compilation of specialized reports authored by both scientists and non-scientists. Moreover, each report is an end product of a series of scientific tests or observations created within a context of various social interactions and potentially mitigating political and economic factors.

The field of Science and Technology Studies has demonstrated that ideologies of scientific neutrality and objectivity are poor guides to how science is actually made.[5] This example of the DPAA-CIL's forensic identification process attempts to challenge the cultural assumptions about the scientific process and to push the attendee to peek into the black box and examine not only the complexity of the science, but the contingencies under which those tests and observations are made. Shining a light on these conditions demonstrates how a forensic identification is as much a social as a scientific process. Most importantly, greater awareness of how identifications are made will allow forensic practitioners to better mitigate biases and improve their identification processes.

Forensic Identification, Anthropological Theory, Scientific Process

A36 The Social Side of Human Identification

Robin C. Reineke, PhD, University of Arizona, 1009 E South Campus Drive, Tucson, AZ 85721*

After attending this presentation, attendees will understand how context-specific sociocultural anthropological expertise can support and enhance the applied work of human identification, especially in violent or post-conflict settings. Focused as it is on social worlds and local contexts, sociocultural anthropology can provide a bridging or mediating role between forensic practitioners and local communities.

This presentation will impact the forensic science community by providing evidence and examples of effective collaboration between forensic practitioners and sociocultural anthropologists in the realm of human identification.

Observations and data used in this presentation come from more than nine years of applied forensic work and research among forensic practitioners at the Pima County Office of the Medical Examiner (PCOME) and families of missing and deceased migrants along the United States-Mexico border. Data are drawn from the Colibrí Center for Human Rights, as well as from interviews with forensic scientists, law enforcement, border patrol agents, non-profit family advocates, and the families of missing and deceased migrants.

This presentation is focused on a specific set of findings, namely that forensic identification processes that fail to take into account political, cultural, and social contexts are not only less effective but may actually cause harm. As victims of violence are often structurally vulnerable, care must be taken so that forensic investigations are undertaken with an awareness of the political context and translated with cultural sensitivity.[1] Without efforts to integrate the family and community into the process, forensic identifications can become medicalized, reproducing violent structures enforced by those in power and disenfranchising the healing process that drives so many forensic practitioners to do the work they do. Medicalization is the process whereby normal human conditions become problems for medical professionals in a manner that often has long-term negative social health consequences.[2] In this presentation, the concept of medicalization is applied to examine forensic practices of human identification: can forensic investigations, especially in violent contexts, serve to medicalize grief in a way that exacerbates the trauma and suffering of affected communities?

Results of long-term participant observation reveal that forensic identifications can indeed cause additional suffering and trauma for families, especially if the identification and notification process is conducted with an approach that is not sensitive to community context and history. Some of the best models for avoiding these problems involve collaboration between sociocultural anthropologists and forensic anthropologists in international human rights (post-conflict) settings. Research for this presentation reveals that there are needs, as well as precedent, for such collaborative approaches within the United States domestic context.

The PCOME is one of the first offices in the nation to integrate local knowledge in a meaningful and sustained manner. By working with social scientists and community advocates, forensic practitioners at the PCOME have been able to revise and improve protocols so they align more closely with family and community needs.[3] The PCOME works closely with the Colibrí Center for Human Rights, a family advocacy organization founded by cultural anthropologists. Colibrí manages an antemortem database relevant to missing migrants and communicates directly with families throughout intake, investigation, and case resolution. Colibrí attends to the social side of identification, which includes explaining all aspects of the investigation to families, fielding their questions, and offering supportive advocacy grounded in a place of understanding and respect for the family's needs. The results of this collaboration include more than 100 successful identifications. Partnerships such as that between the PCOME and Colibrí model a best practice where efforts are made to link the "affective identification" made by families with the scientific identification made by forensic practitioners.[4]

The scientific process of human identification cannot be entirely separated from the social context in which it operates. If the family does not trust, understand, or have a stake in the work of forensic practitioners, positive identifications will do nothing to assist families and communities in healing. There is an entire other side to the identification process that is critical — the social side of identification. If the social side is not connected to the scientific side of identification, forensic work can become imposed on communities in harmful ways. Collaboration between forensic practitioners and sociocultural anthropologists is offered as a step forward in both international and domestic contexts.

Identification, Migration, Sociocultural Anthropology

A37 Family Opposition to Human Rights Exhumations: The Need for Interdisciplinary Research on a Question of Science, Politics, and Consent

Adam R. Rosenblatt, PhD, Haverford College, 370 Lancaster Avenue, Haverford, PA 19041*

After attending this presentation, attendees will understand how ethnographic, historical, and political science research can clarify the reasons why some family members have opposed the exhumation of mass graves and identification of missing persons, even in cases in which those efforts are framed as "transitional justice" work and fueled to a great extent by concern for the needs of these very families.

This presentation will impact the forensic science community by addressing a topic that some experts allege "has been largely, shamefully avoided in forensic anthropology literature": the objections of a key group of stakeholders, families of the missing, to the exhumation and identification of their dead.[1] It is a crucial topic because of the ways in which it pits three priorities widely acknowledged as important — the creation of an objective historical record, the collection of evidence, and the needs of families of the missing — against one another.[2] On the occasion of the 2014 decision to change the name of the Physical Anthropology Section to "Anthropology" and the 2015 opening of the AAFS Humanitarian and Human Rights Resource Center, this presentation illustrates a crucial area in which new interdisciplinary connections can be made between the practical challenges of forensic science in the human rights context and emerging sociocultural studies of the needs of families of the missing in post-conflict regions.

Based on eight years of research, including archival research in two languages and interviews with forensic anthropologists, human rights activists, and religious leaders, this presentation identifies two broad categories of objections to post-conflict exhumations: religious and political; however, in this process, it argues for a nuanced understanding of the connections between the two: religious objections can serve political purposes and political objections can be infused with notions of the sacred.

While cultural and religious objections to both exhumation and autopsy can impact death investigation in any context, these objections are particularly complex in post-conflict areas in which forensic science comes to be seen not only as mechanism for medicolegal truth, but also as a "technology of repair" and of memory for divided societies.[3,4] In Poland and the Democratic Republic of the Congo, forensic anthropologists have faced not only religious prohibitions against exhumation, but also complex questions about the extent to which the religious leaders and community members who were making these objections spoke for the interests of all families of the missing or for all survivors of violence. As they made decisions about whether and how to proceed with exhumation efforts, they were hampered by a lack of supporting sociocultural research into the political pressures that informed these religious objections and other questions of power and representation in these communities.[5]

Other types of objections, more political in thrust, are unique to the circumstances of human rights and transitional justice — particularly because of the ways in which human rights violations organize networks of victims and systematize their claims.[6] The first and still best-known mobilization against forensic investigations into human rights violations occurred in Argentina, starting in the mid-1980s, when Clyde Snow and the Argentine Forensic Anthropology Team began exhuming the graves of "disappeared" victims of right-wing political repression. The anthropologists faced protests from Argentina's most famous group of human rights activists, the Madres de Plaza de Mayo, who demanded that legal accountability for the perpetrators of violations be prioritized before any form of identification, mourning, or "closure."[7] The Madres' organizing slogan, "Aparición con vida" ("Let the disappeared alive") lent the appearance of irrationality to a group of activists whose family members were, except for a few extraordinary cases, almost certainly dead.[8]

This presentation joins other scholars in finding it unacceptable to dismiss anti-exhumation sentiment — religious or political — as the irrational demands of "superstitious" cultures or of people traumatized by grief.[9,10] It calls for both data-sharing across context and sociocultural analysis of the widespread phenomenon of these objections in order to promote informed critical engagement. The reasons for family members' views on exhumation are multi-dimensional — political, moral, historical, and sometimes scientific — and often contain both important insights and misrepresentations. Only through both comparative and deeply contextual understandings can forensic anthropologists be adequately prepared for principled negotiation of this important challenge.

Human Rights, Families, Anti-Exhumation

A38 Morphological and Metric Study of the Nose and Ear in a North Indian Population: Forensic Anthropological Context

Kewal Krishan, PhD, Panjab University, Dept of Anthropology, Sector 14, Chandigarh 160 014, INDIA; Tanuj Kanchan, MD, Dept of Forensic Medicine, Light House Hill Road, Mangalore, Karnataka 575 001, INDIA; and Manojit Chakraborty, MSc, Panjab University, Department of Anthropology, Chandigarh 160014, INDIA*

After attending this presentation, attendees will understand the importance of the variability in appearance of the nose and ear in a north Indian population, which will also strengthen knowledge in facial forensic identification of victims of mass disasters and in crime scene investigations.

This presentation will impact the forensic science community by presenting new information on the uniqueness and variability in the appearance of the nose and ear in a north Indian population and their usefulness in forensic facial identifications.

Facial reconstruction is an important aspect of forensic anthropology which helps in establishing the identity of the deceased or the perpetrator of a crime. Facial reconstruction can be achieved by a forensic scientist/facial anthropologist using the original skull, a replica, or clinical images of the skull. Another method of facial reconstruction involves photographic records and Closed-Circuit Television (CCTV) images of the various features of the face wherein a forensic artist reconstructs the face with the aid of additional information gathered from acquaintances. Ear and nose patterns provide important and useful information for facial reconstruction. When dismembered and mutilated human remains are recovered, the individualistic features of the nose and ear can help in the identification of the deceased.

The present study was conducted with a view to evaluating metric, morphological, and unique features of the nose and ear among young adults in a north Indian population. The data were collected from a sample of 215 participants (104 males and 111 females) between 18 years and 25 years of age. The study evaluated the inter-individual variation and sex differences in morphological and metric features of the nose and ear. The morphological features of the nose and ear, such as nasal root, nasal bridge, nasal profile, nasal septum, nostril shape, nasal wings, shape and size of the ear, shape, size, attachment, and thickness of the ear lobe, shape of the tragus, helix, Darwin's tubercle, and hypertrichosis, were examined in this sample. General metric measurements of the nose and ear were gathered for baseline data.

The results indicate that the overall dimensions of the nose and ear in males were found to be significantly larger than females. Bilateral variations were observed for some of the measurements. No significant sex differences were found in the nasal index (males=64.98, females=65.57). Similarly, the left and right ear indices were not significant (for the left ear, males=57.53, females=56.40; for the right ear, males=56.49, females=55.49). The morphological parameters of the nose were found to be quite variable in both sexes. Significant variations existed in nasal profile, nasal tip, nasal septum, nostril shape, and thickness of nasal wings. For the morphological parameters of the ear, oval-shaped ears were quite common (80.77% in males and 72.07% in females). A squarish-ear lobe (41.34% in males and 74.77% in females) was more frequently observed than other types. Attached ear lobes were found in 55.77% of males and 82.89% of females. A normally rolled helix was present in 62.50% of males and 79.28% of females. Darwin's tubercle was found among 5% of the study population. Hypertrichosis was observed in approximately 13% of the males.

Facial Identification, Nose and Ear, North Indians

A39 Morphologic Analysis of the Location of the Lens on the Orbit Using 3D Reconstructed Models

Dong-Ho Eddie Kim, BSc, 222 Banpo-daero, Seocho-gu, Seoul 137-701, SOUTH KOREA; Yi-Suk Kim, MD, PhD, Ewha Womans University, Dept of Anatomy, School of Medicine, 911-1, Mok5-dong, Yangcheon-gu, Seoul 158710, SOUTH KOREA; Dae-Kyoon Park, MD, PhD, Soonchunhyang University, Department of Anatomy, College of Medicine, 31 Sooncheonhyang 6-gil, Dongnam-gu, Cheonan-si, Seoul 31151, SOUTH KOREA; In-Beom Kim, PhD, The Catholic University of Korea, 222 Banpodaero Seochogoo, Seoul 137701, SOUTH KOREA; and U-Young Lee, MD, The Catholic Univ of Korea, Dept of Anatomy, Coll of Med, 505, Banpo-dong, Seocho-gu, Seoul 137701, SOUTH KOREA*

After attending this presentation, attendees will understand the sex differences found using 3D models and landmark coordinates for eyeball placement and the development of regression formulas for lens protrusion. In addition, morphometric characteristics of the orbit according to sex and the use of regression formulas to find the location of the lens center for use in forensic facial reconstruction will be presented.

This presentation will impact the forensic science community by illustrating the sex differences in orbital morphology and a reliable location of the lens for fontal and lateral views. In addition, the regression formulas are developed in this study to find the most probable lens protrusion location.

The goal of this research is to study the relationship between the lens location and the orbit-related structures for eyeball placement in forensic facial reconstruction. A total of 200 high-resolution cranial Computed Tomography (CT) scans were studied. The sample was composed of 100 men and 100 women, with age ranges of 21years to 70 years; the overall mean age was 46 years. The 3D cranium and lens models were reconstructed from the Digital Imaging and Communications in Medicine (DICOM) data using the Mimics® version 16.0. Ten distinct landmarks were indicated on the cranium and lens models. A total of 25 morphological and angular measurements between landmarks including the lens center were measured by the Mimics® software and were analyzed by the Statistical Package for the Social Sciences (SPSS) version 20.0.

The study results describe general orbit morphology and interpret the relationship between orbit-related structures, including the lens center. First, there were sex differences in the orbital morphology and these results match other data of generalized orbital-morphologic differences in males and females. Males had more developed eyebrows and a more receding inferior orbital rim. In addition, males had a bigger orbit and the orbit was rotated in a more clockwise manner. Second, there were no sex differences in lens location; the location of the lens can be estimated regardless of sex. On the frontal view, the lens can be placed at the point of 55.59% of Medial Orbitale (MO)-Lateral Orbitale (LO) breadth horizontally and 48.40% of Superior Orbitale (SO)–Inferior Orbitale (IO) height perpendicularly. On the lateral view, the lens can be placed approximately 1.11mm in front of Orbitale Tangent Plane (OTP) line. In addition, more sophisticated methods using regression formulas can be used to estimate the lens protrusion. The presented first formula is the traditionally used regression formula that is modified for use in Korean populations. The next two formulas are proposed in this study to improve the reliability of lens protrusion, as the first formula has a low $R^{2\ value}$. The morphometric characteristics of the orbit, including the lens center and the regression formula to estimate the location of the lens center, will be helpful for forensic facial reconstruction.

Lens Location, Orbit, Facial Reconstruction

A40 A Challenging Case of Facial Reconstruction of a Suicide by Jumping From a Height

Luigi Cipolloni, MD, PhD, Viale Regina Elena, 336, Rome 00161, ITALY; Alessandro di Luca, MD, Via Domenico Chelini 7, Rome 00197, ITALY; and Laura Donato, Via Tripolitania 195, Rome 00199, ITALY*

After attending this presentation, attendees will better understand an experimental, alternative method of facial reconstruction that substitutes artificial supports for missing or degraded bony elements in cases of heavily disfigured victims.

This presentation will impact the forensic science community by showing how this method of facial reconstruction could be useful in cases where the bony elements of the face are completely destroyed and are unsuitable for facial identification.

In a forensic context, the process of identification is complementary to the forensic examination. In cases of highly decomposed or skeletonized unknown decedents, the intervention of the forensic anthropologist can provide additional information about age at death, sex, and other parameters that cannot be easily detected due to the lack of soft tissues.

A crucial part of the identification process is comprised of the facial reconstruction: this procedure is based on rebuilding the soft tissues and the physiognomic general aspect of the victim's face. The skull represents the skeletal support, and standard soft tissue depths are applied to specifics landmarks. The result is a 2D or 3D representation of the features belonging to the non-identified body. The skeletal tissue supplies a solid support whereby tissue depth can be placed: by these means, it is possible to consider the variability of the skull morphology and the rendering of the application of standard tissue depth.

The present study was challenged by the case of a 33-year-old woman who committed suicide by jumping from a window of her flat. Her face was heavily disfigured by the impact from the fall. The main trauma was directly to the head and this completely destroyed the facial features. The bony supports of the cranium were fractured and impossible to reconstruct, as various fragments were also missing. Only the mandible was present, but was broken into two pieces; however, it did allow for some observations of the morphological structures of the chin.

In order to reconstruct the anatomic distribution of the facial tissues, an artificial support was used to simulate the missing bone structures. In classical reconstruction techniques, the process performed is usually just the opposite — artificial soft tissues are fixed onto the bone structures. In this case, the landmarks had to be fixed on the soft tissues and then applied onto a solid support, a polystyrene form simulating a human head. The edges of lacerated skin were stitched and fixed on the structure with pins. After the facial reconstruction, the result was photographed: graphical elaboration was necessary in order to delete the evidence of lacerated skin and make it suitable for identification purposes.

The creation of an artificial support, substituting the skull, allowed for the rebuilding of the physiognomic facial traits, yielding a positive comparison result to a photograph of the possible subject. Furthermore, the facial reconstruction supplied additional information about the exact site where the subject's head impacted the ground.

Forensic Anthropology, Facial Reconstruction, Identification

A41 The Perceived Accuracy of 3D Facial Reconstructions

Eileen M. Schilling, MSc, 613 Cayman Avenue, Holly Springs, NC 27540*

After attending this presentation, attendees will be aware of the implications of possible identification from 3D facial reconstructions.

This presentation will impact the forensic science community by showing that leads generated by 3D facial reconstructions should be viewed with caution and are generally unreliable.

Often 3D facial reconstructions are a final effort to lead to the identification of skeletal or decomposed remains of an individual, when all other methods have failed to provide leads to identification. Generally, 3D facial reconstructions are considered to be inaccurate because their accuracy relies on the connection between the reconstruction and a living individual. This study tested the accuracy of 3D facial reconstructions in three ways: (1) by assessing the perceived accuracy of a facial reconstruction when compared to a known individual; (2) assessing the consistency of reconstructions created using the same protocol; and, (3) assessing the consistency of the raters.

For this study, 11 different participants each created one facial reconstruction from a cast of the same known individual. Each of the participants completed the reconstructions following the same protocol. After the reconstructions were completed, photographs were taken of each reconstruction. The experiment was evaluated in two parts: (1) a likeness rating of each reconstruction against an array of seven individuals of similar age, race, and sex as the known individual; and, (2) biometric comparison of the reconstructions to the known individual. For the likeness ratings, each rater was asked to rate each of the reconstructions against the array of photographs and provide a score from one (the reconstruction looks nothing like the person) to ten (the reconstruction is of that person). After these ratings were completed, the raters were informed of which photograph was the known individual and asked to rate the reconstructions again, but against only the known individual. Five standard biometrics measurements were taken: forehead to tip of the nose, tip of the nose to the chin, distance between middle of the eyes, width of the mouth, and total length of the face.

The ratings data was analyzed using a Kendall's coefficient of concordance. This allowed a determination of inter-rater agreement for each of the reconstructions. All reconstructions except one showed statistical significance ($p<0.05$), indicating that there is agreement between the scores assigned to each reconstruction from the different raters. For one reconstruction, there was no agreement among the raters. Inter-rater reliability for the photograph of the known individual, while the individual remained unknown to the raters, was tested. None of the reconstructions returned statistically significant results against the known, with significance levels of $p\geq0.993$. The ratings acquired after the known individual was revealed to the raters showed similar inconsistencies in the ratings, with significance levels of $p\geq0.990$. Subsequently, the biometric measurements were analyzed using a one-sample *t*-test. Only one of the measurements, the width of the mouth, was not statistically different ($p=0.406$) from the measurement of the known individual. The other four measurements showed statistical significance ($p<0.05$), indicating that those measurements are statistically different from the known individual's measurements.

The results address two main issues with facial reconstructions. The first is that without an accurate initial outline of the face, any evaluation of the accuracy of the reconstruction cannot be considered to be a true indication of its accuracy. The second issue is how individuals perceive a face cannot truly be tested if the initial face (i.e., the reconstruction) is too inaccurate to be recognized as the individual it is intended to be. Since facial reconstructions rely on individuals recognizing a face they are familiar with, the fact that none of the raters knew the individual they were supposed to be identifying may have hindered their recognition of the reconstructions as that person. Further research should focus on the accuracy of the initial outline of the face to increase accuracy of overall facial reconstructions.

Facial Reconstruction, Accuracy, Perceived Accuracy

A42 Application of Enhanced Point Estimators on a Sample of *In Vivo* Computed Tomography (CT) -Derived Facial Soft Tissue Thicknesses

Kelsey Kyllonen, MA, 2501 Investigation Parkway, Quantico, VA 22135; Connie L. Parks, MA, Federal Bureau of Investigation, 2501 Investigation Parkway, Laboratory Division, Quantico, VA 22191; and Keith L. Monson, PhD, 2501 Investigation Parkway, Quantico, VA 22135*

After attending this presentation, attendees will better understand the level of congruence between the conventional arithmetic mean and the shorth and 75-shormax statistics for facial soft tissue depths.

This presentation will impact the forensic science community by providing the results of further investigation into the conventional use of average facial soft tissue depths and the applicability of an alternative statistical technique for measuring central tendency. Additionally, this presentation will provide support for the standardization of best practices in regard to facial soft tissue research.

Facial approximation refers to the process of approximating an antemortem representation of an unidentified individual from his or her skull. This representation is commonly achieved by applying and modeling clay directly to the individual's skull or a skull replica while utilizing the bone morphology as a construction guide. Facial soft tissue depth measurements are a key component in the development of an effective facial approximation. Soft tissue depth research has an extensive and productive history, encompassing more than a century of investigation and employing an expansive array of collection methodologies, analyses, and populations. One common strategy across facial soft tissue depth research is the use of the arithmetic mean as the primary central tendency descriptor. While the arithmetic mean is an informative statistic, some researchers argue that it is not a robust descriptor of central tendency in datasets exhibiting skewed distributions and thus may not reveal the true attributes of a tissue depth dataset. The purpose of this study is to illustrate application of the facial soft tissue depth analysis tool TDStats R to a contemporary American tissue depth dataset and explore the level of congruence between the arithmetic mean, shorth, and 75-shormax statistics.[1,2]

Facial soft tissue depth measurements were collected from cranial Computed Tomography (CT) scans of 388 living American adults.[2] The scans included males (n=198) and females (n=190) from four self-identified ancestry groups ranging in age from 18 years to 62 years (mean: 31, median: 30). Although ages and weights varied considerably, no individuals were eliminated from the study. Two experienced researchers independently collected 14 midsagittal and 11 bilateral soft tissue depths for each CT scan. Summary statistics, including the shorth and 75-shormax, were calculated for the 25 tissue depths using TDStats R.[1] Differences between arithmetic mean and shorth values for the 25 tissue depths ranged from 0.1mm to 2.3mm (average 0.6mm), with no difference exceeding one Standard Deviation (SD) of the mean. In addition, differences between the arithmetic mean and 75-shormax values for the tissue depths were approximately one SD of the arithmetic mean for many tissue depth points, and none exceeded two SD. Differences between the arithmetic mean and 75-shormax mean tended to be greatest for the midfacial region.

These findings suggest that the mean and shorth values of the study sample are congruent within ±1 SD. The results also indicate that 75-shormax values include ±1 to 2 SD of the mean. Although no practical difference between the arithmetic mean, shorth, and 75-shormax statistics was observed in this tissue depth dataset, the statistics may still prove beneficial for analysis of tissue depth datasets. Although shorth values may better represent skewed distributions, they will regress to the arithmetic mean when applied to normally distributed data.

Facial Approximation, Facial Reconstruction, Tissue Depths

A43 Evaluation of the Facial Soft Tissue Thickness in the Living in a Brazilian Population: Pilot Study

Antonio A. Antunes, PhD, Rua Cardeal Arcoverde, 267, Graças, Recife, Pernambuco, BRAZIL; Hugo L. Albuquerque, Faculty of Dentistry - University of Pernambuco, Av. General Newton Cavalcanti, s/n, Camaragibe, BRAZIL; Evelyne P. Soriano, PhD, Faculty of Dentistry, University of Pernambuco, Av. General Newton Cavalcanti, s/n, Camaragibe, BRAZIL; Marcus Vitor D. Carvalho, PhD, Faculty of Dentistry, University of Pernambuco, Av. General Newton Cavalcanti, s/n, Camaragibe, BRAZIL; Reginaldo I.C. Campello, PhD, Faculty of Dentistry, University of Pernambuco, Av. General Newton Cavalcanti, s/n, Camaragibe, BRAZIL; and Gabriela G. Porto, PhD, Faculty of Dentistry, University of Pernambuco, Av. General Newton Cavalcanti, s/n, Camaragibe, BRAZIL*

After attending this presentation, attendees will better understand creating a database reference thickness of the soft tissues in the living population of Recife, Brazil, according to age, sex, and Body Mass Index (BMI).

This presentation will impact the forensic science community by providing results on the possibility of forming a database that can help forensic anthropological practices and procedures of human identification, more specifically for the identification of human skeletal remains. As a result of this method, it would be possible to acquire an image of the unknown individual based on average values of the soft tissue thickness in specific populations obtained, which can allow the recognition of an individual.

Currently, there is a huge demand for human identification, as well as decedent or skeleton recognition. Several methods of identification are described in each of these situations, depending on if the subject is alive or dead or is in a cadaverous or skeletal stage.[1] Thus, for human skeletal identification remains, a variety of methods are cited, such as DNA analysis and tooth radiographs.[2] Although these methods provide important information for forensic scientists about age, sex, and deceased body size, many may not be useful because they depend on the availability of a comparative material, either from police, dentists, or relative's databases.[3] Facial reconstruction is the last option when other identification methods have failed. Data on the soft tissue thickness represent an integral part of the paths to obtain the approximation of the individual's face.[4] Previous studies show that different populations exhibit significant variation in the thickness of the soft tissue being questioned and whether data of a population may be applied in facial reconstruction with different ancestry.[5,6] Thus, for obtaining an accurate facial reconstruction, the construction of a database of soft tissue thicknesses to a specific population is required. In the Brazilian population, literature is scarce and there are only records of studies dealing with cadavers.[6]

A cross-sectional and prospective study was performed. Data collection was conducted in patients from the Oswaldo Cruz Hospital, University of Pernambuco (HUOC/UPE) radiological clinic who had Computed Tomography (CT) scan examinations. Collected CTs were measured for facial soft tissue thicknesses in 20 selected craniometric points: supra-glabella, glabella, nasion, rhinion, midphiltrum, supra-dental, infra-dental, supra-mental, pogonion, mentual, supra-orbital, infra-orbital, lateral-orbit, inferior zygomatic, zygomatic arch, supra-glenoid, gonion, supra-M2, occlusal line, and sub-M2. For the comparison between categories of independent variables in relation to means, Student's t-tests with equal variance were used, Student's *t*-tests with unequal variances or Mann-Whitney tests in cases of comparisons between two categories were undertaken, and the *F*-test Analysis of Variance (ANOVA) or Kruskal-Wallis comparisons were used for more than two categories.

The total sample consisted of 30 patients, 15 men and 15 women, aged between 12 years and 78 years old. The mean age was 42.93 years, with slightly more than half (53.3%) 40 years of age or older. Most individuals had brown skin color, followed by 23.3% of the sample who were Black and 10.0% who were White. The average weight, height, and BMI were 69.57kg, 1.65m, and 25.53, respectively. The two highest percentages corresponded to those who were overweight (36.7%) and eutrophic (33.3%) and the lowest corresponded to those who were malnourished (10.0%). It was observed that with the exception of the distances or measures D9, D13, D15, D18, and D20 that had higher averages in females than in males, the other average measurements were correspondingly higher in males, though with significant differences between the sexes ($p<0.05$) in distances D1, D3, D4, D5, D6, D7, D13, and D17. Regarding BMI, the study showed that the measure D9 (pogonion) was the only one with significant differences; the average was lower among the malnourished (7.81), followed by the eutrophic (9.78), and the range was 11.85 to 12.63 between the obese and overweight, with significant differences between the malnourished and those who were overweight and obese and among the eutrophic with those who were overweight.

It can be concluded that significant differences between age groups for any of the evaluated measures and between the sexes ($p<0.05$) in distances D1, D3, D4, D5, D6, D7, D13, and D17 were present. Only one point (D9) varied significantly from BMI.

Soft Tissue Thickness, Computed Tomography, Facial Reconstruction

A44 Applications of 3D Technology in Forensic Anthropology

Helen Cho, PhD, Davidson College, PO Box 6934, Davidson, NC 28035; Eun Jin Woo, PhD*, Seoul National University, Dept of Anthropology, San 56-1, Silim-dong, Kwanak-gu, Seoul, SOUTH KOREA; Hae Joung Cho*, MAKRI in Hyunchungwon, Dongjack-gu, Seoul, SOUTH KOREA; Yu Ryang Jang, PhD*, 65 Hyeonchung-ro Donggak-dong, Donggak-gu, Seoul 156-080, SOUTH KOREA; and Nahyok Im, PhD*, 65 Hyeon Chung-Ro, Dong Jak - Gu, Seoul 156-080, SOUTH KOREA*

After attending this presentation, attendees will better understand the different types of 3D technology and their applications in forensic anthropology and related forensic disciplines.

This presentation will impact the forensic science community by providing results that compare various 3D scanning systems and the quality of the models produced. This presentation encompasses a relatively new type of technology and novel applications in forensic anthropology and related disciplines such as forensic art.

With the advent of 3D technology, the potential applications are numerous in the forensic sciences. Forensic anthropology and related disciplines, such as forensic art, can benefit from 3D imaging technology and 3D printing of skeletal remains. One of the main objectives of forensic anthropology is to reconstruct the biological profile of the unknown skeletonized individual. Whether the remains are positively identified and should be returned to the next of kin, or unidentified and kept in custody, the bony remains may be needed for anthropometric analyses and facial reconstruction. Both 2D photography and scanned images may be insufficient for further anthropometric analyses if the original remains are unavailable for pragmatic reasons. Performing facial reconstruction on the actual skull may be impermissible, and utilizing the real human remains as physical models in court while serving as an expert witness may be deemed unethical and disturbing to the audience. Furthermore, rare anatomical and anthropological specimens can be reproduced for educational purposes. Thus, 3D technology can be a necessary tool for forensic anthropologists to create replicas of the skeletal remains.

In this regard, the most important issue is the quality of the 3D model. Anthropometry requires precise measurements of standardized osteological landmarks, and these quantified data are then employed to derive the biological profile of the unknown individual. The quality of 3D replicas is dependent on image resolution and digitizing systems. Although digitizing natural bone at a high resolution will result in a more precise model, access and availability of the best digitizing system and the 3D printer may be limited to organizations such as law enforcement and universities. In this study, the quality of the anatomical models created from a single 3D printer using various digitizing systems was compared.

Three different techniques were employed to digitize a skull at the Central Identification Laboratory in the Ministry of National Defense in Seoul, Korea. Three separate systems were printed with the Zprinter® 650 powder-based 3D printing technique utilizing a powder composed of plaster and a starch/cellulose mixture at the speed of 28mm per hour. The digitizing systems were as follows: (1) Computed Tomography (CT); (2) an ATOS 1 (0.8M) 3D scanner with software that captures the image in an 800,000-pixel triangle mesh; and, (3) a PHT-6500 panorama X-ray with a rotating X-ray tube that captures a panoramic image of the object. To test the quality of the replicas, 34 standard cranial measurements (e.g., nasal height, bigonial width, mandibular angle) were collected from the original skull and the CT, ATOS 1, and PHT-6500 models for comparison.

Based on the results of this study, although CT scans produce the highest resolution images in general, it may be unnecessary to rely only on CTs when comparable technology is available and more accessible.

3D Printing, 3D Scanning, Anthropometry

A45 Automated Anthropometric Measurements of Long Bones Using Point Cloud Data

Lisa M.M. Van Den Broek, Weg Naar Geneuth 121, Maasmechelen 3630, BELGIUM; Thera McAvoy, MSc, PO Box 8945, Albuquerque, NM 87198; Roland Wessling, MSc, Cranfield Univeristy, Cranfield Forensic Institute, Shrivenham, Oxfordshire SN6 8LA, UNITED KINGDOM; Jessica Bolton, MSc, Cranfield University, Cranfield Forensic Institute, Defence Academy of the United Kingdom, Shrivenham SN6 8LA, UNITED KINGDOM; Jelana Bekvalac, MSc, Museum of London, 150 London Wall, London EC2Y 5HN, UNITED KINGDOM; Anja Leipner, Institute of Forensic Medicine, University of Zurich, Winterthurerstrasse 190/92, Zurich 8057, SWITZERLAND; and Michael Thali, MD, Universitat Zurich, IRM / Forensic Institute, Winterthurstrasse 190/52, Zurich CH-8057, SWITZERLAND*

After attending this presentation, attendees will understand the current and future potential for traditional osteometry to be enriched by the application of software capable of producing automated osteometric measurements, thus reducing the risk of intra- and inter-observer error.

This presentation will impact the forensic science community by demonstrating that 3D point clouds created from both dry bones and medical Computed Tomography (CT) scans can be modeled and automatically measured. This proof of principle strongly indicates that future development in this field will allow the majority of traditional anthropometric measurements to be made with software programs either fully or semi-automatic, without the need of manual intervention. These measurements will be repeatable, reproducible, and can overcome the lack of universal measurement standards within forensic anthropology, which makes it specifically relevant for the forensic aspect of anthropology.

Osteometry is widely used and accepted in the forensic, archaeological, and anthropological world. This is to establish a biological profile, which typically includes sex, age, stature, and ethnicity of an individual by using regression formulas that require measurements of various bones and bone regions. The accuracy of these measurements is partially determined by how much experience the practitioners have, as well as where each practitioner chooses to take measurements, as there are no clearly defined or universally accepted best practices.[1-3]

With current technology, it is possible to create detailed 3D models of bones and perform measurements on them. Previous studies show that measuring 3D models, produced with CT scanners or hand-held laser scanners, are equally as accurate as when physically measuring on a dry or fresh bone.[4,5]

Two studies were performed, one with 31 dry femora from the St. Brides Church Crypt collection in London, England, and one using 40 femora from CT scans provided by the Institute of Forensic Medicine at the University of Zurich, Switzerland. The maximum length was obtained from the dry bones with an osteometric board and manually from 3D models of the CT scans in MeshLab. The maximum length of the point clouds was then obtained automatically within custom software. Due to the pioneering nature of these studies, multiple methodologies for data handling and analysis were developed and tested in order to determine their feasibility prior to the creation of the custom software.

The results of these studies show clear correlations, which provide evidence that measurements taken automatically by software are as good as those taken manually, and thus has the potential to be used for biological profiles. This would have the advantage of allowing practicing forensic anthropologists to present easily reproduced and quantifiable results.

3D Models, Automated Measurements, Virtual Skeletal Analysis

A46 Introducing Standardized Anthropological Measurement Protocols for Postcranial Bones Using 3D Surface Reconstructions in Computed Assisted Design (CAD) Software

Mikaela S. Reynolds, MSc, Level 5 Q Block,, 2 George Street, Gardens Point, Brisbane, Queensland 4001, AUSTRALIA; Donna M. MacGregor, MSc, Queensland University of Technology, School of Biomedical Sciences, Faculty of Health, Gardens Point Campus, Brisbane, Queensland 4001, AUSTRALIA; Mark D. Barry, MS, Queensland University of Technology, High Performance Computing and Research Services, 2 George Street, Brisbane, Queensland 4001, AUSTRALIA; Nicolene Lottering, BS, Queensland University of Technology, School of Biomed Sci, Faculty of Health, 2 George Street, Gardens Point, Brisbane, Queensland 4001, AUSTRALIA; and Laura S. Gregory, PhD, Queensland University of Technology, School of Biomedical Sciences, Gardens Point Campus, Brisbane, Queensland 4001, AUSTRALIA*

After attending this presentation, attendees will appreciate the improved accuracy and reliability attributed to semi-automated anthropological measurement protocols on 3D reconstructions of postcranial bones using CAD software.

This presentation will impact the forensic science community by demonstrating the benefits of Multi-Slice Computed Tomography (MSCT) and the advances of a virtual approach as a non-invasive method for obtaining reproducible morphometric information in anthropological investigation. The visualization and measurement capabilities of reverse engineering software will be discussed. The protocol introduced in this study and the precision testing results presented are essential for advancing current medicolegal death investigations, accentuating the advantages of "virtual anthropology."

Consistent with the International Criminal Police Organization (INTERPOL) Disaster Victim Identification Guide, postmortem identification during mass disasters systematically involves the utilization of MSCT. Specifically in Australia, postmortem MSCT was regarded as a valuable tool in disaster victim identification during the 2009 Victorian Bushfires and constitutes standard protocol for external autopsy in a number of Australian mortuaries. The 3D surface-rendered models in CAD software has the potential to increase measurement accuracy in comparison to Multi-Planar Reformatted (MPR) assessment, which uses contiguous 2D orthoslices, where the outer boundary of macroscopic bony landmarks may be arduous to determine. Utility of MPR models also requires a considerable level of anatomical imaging knowledge, as the investigator is required to mentally construct a 3D representation from 2D images.

The goal of this present study was to introduce a contemporary osteometric protocol using CAD software and to conduct observer error testing to assess the reliability of this protocol. Six thin-slice Digital Imaging and Communications in Medicine (DICOM) datasets (thickness: 2mm, overlap: 1.6mm, voxel size: 0.78mm x 0.78mm x 2.0mm) of the femoral region of contemporary adult Australian individuals (aged neonate to 75 years old) were accessed from the Skeletal Biology and Forensic Anthropology Virtual Osteological Database. The femora were subject to manual segmentation to produce an isosurface model compatible with the engineering software program Geomagic Design X™ for osteometric examination. In Geomagic Design X™, the principal component axes were realigned for the construction of a series of anatomical reference planes required to depict a "virtual osteometric board." With reference to silhouette curves, extreme position planes corresponding to the outermost boundary of the isosurface are identified in order to obtain automated plane-to-plane measurements. Bicondylar length and epicondylar breadth were measured by four observers differing in CAD software experience over three separate days to evaluate intra- and inter-observer error. Technical Error of Measurement (TEM), relative Technical Error of Measurement (%TEM), and Intraclass Correlation Coefficient (ICC) were calculated to quantify the measurement error variance and observer agreement of the protocol.

Intra- and inter-observer error results demonstrate that the linear measurement protocol introduced is highly repeatable. Specifically, intra-observer error resulted in %TEM=0.10, ICC=1.000 (CI=0.999-1.000) for bicondylar length, %TEM=0.19, ICC=0.995 (CI=0.980-0.999) for epicondylar breadth. Inter-observer error resulted in %TEM=0.50, ICC=0.995 (CI=0.978-0.999) for bicondylar length, %TEM=0.20, and ICC=0.996 (CI=0.979-1.000) for epicondylar breadth. Since these results are within the acceptable levels of agreements for anthropometric measures, it is recommended that this protocol be implemented in anthropological casework and contemporary anthropological research.

The protocol introduced in this study utilizes high-quality 3D models, which allow "hidden features" such as the medullary cavities to be observed, with the software also providing the opportunity for novel geometric morphometric methods to be developed. A further benefit of CAD software is the use of automated plane-to-plane measurements, which eliminates the requirement of manual identification of landmarks, also reducing the subjectivity associated with the alignment of the bone in MPR protocols.

As it is crucial that all contemporary scientific methods are validated and standardized, this study introduces a technologically new, standardized protocol for linear measurement of postcranial bones using 3D surface reconstructions, with observer error testing demonstrating strong observer agreement. It is therefore suggested that 3D isosurface models using CAD software can be utilized for osteometric assessment of human remains. In addition, this presentation will emphasize the wide application of this protocol, demonstrating standard anthropological measurement of other skeletal elements of the postcranial skeleton (e.g., humerus and scapula) inclusive of subadult long bones.

MSCT, Reverse Engineering, Observer-Agreement

A47 Virtual Skeletal Analysis (ViSA) — One Possible Future for Osteometrics

Roland Wessling, MSc, Cranfield Univeristy, Cranfield Forensic Institute, Shrivenham, Oxfordshire SN6 8LA, UNITED KINGDOM; Sophie Beckett, PhD, Cranfield Forensic Institute, Defence Academy of the United Kingdom, Shrivenham, Swindon, Wiltshire SN6 8LA, UNITED KINGDOM; Jessica Bolton, MSc, Cranfield University, Cranfield Forensic Institute, Defence Academy of the United Kingdom, Shrivenham SN6 8LA, UNITED KINGDOM; Alice Jenny Butcher, BSc, Cranfield University, Cranfield Forensic Institute, Shrivenham, Oxfordshire SN6 8LA, UNITED KINGDOM; Lisa M.M. Van Den Broek, Weg Naar Geneuth 121, Maasmechelen 3630, BELGIUM; and Thera McAvoy, MSc, PO Box 8945, Albuquerque, NM 87198*

After attending this presentation, attendees will better understand what has already been achieved in moving from physical osteometrics and qualitative anthropological assessments to virtual, digital, and quantitative analysis. Furthermore, the current and future opportunities and possibilities in this field will be outlined to enable attendees to develop their own research in this area.

This presentation will impact the forensic science community by detailing the processes involved in ViSA and the considerable range of low and high equipment, software, and methodologies involved. This will show that digital bone analysis can be performed with very few and affordable facilities and that the real challenge is the development of entirely new methodologies and in not acquiring complex hardware and software.

Osteometry and its use in establishing biological profiles has long been researched and practiced by anthropologists. Traditionally, it is done on physical, dry bones or bone regions using calipers and osteometric boards. Landmarks on bones are identified by the anthropologist and used to measure and record the various distances that can be used to determine, or at least estimate, age, sex, stature, and ancestry.

Through the development of imaging technology, from digital cameras to Computed Tomography (CT) scanners, a new way of doing osteometrics has been developed. There are two main processes involved: scanning and data analysis. The scanning or data creation can be accomplished in various ways, such as photogrammetry, laser or light scanning, and CT scanning. Different methods have different advantages and disadvantages.

The raw data then needs to be processed to create a 3D representation of an actual bone or bone region. Various software packages are being used for this and much is currently being done manually; however, research is being carried out to establish reliable automated processes to make this aspect far more efficient. The virtual bone model can then be analyzed and this is currently being done with either software that was written for a different purpose, such as Geographic Information Systems software or software that is written specifically for research projects. Some researchers carry out their osteometric measurements manually on the virtual bone while others attempt to develop software that detects bones, bone regions, and landmarks automatically or semi-automatically and then perform the osteometric measurement equally automatically.

While the idea of not using an actual, physical bone and not measuring it with an equally real tool will no doubt irritate some anthropologists and evoke considerable opposition, there are a number of advantages to be considered, some of which are: (1) scanned bone data files can be stored permanently with far less logistical effort compared with real skeletal remains; (2) virtual bone models can be produced from the living or from decedents who are fully fleshed; (3) population-specific data could be produced for any region on Earth from living populations; (4) analysis of virtual bones can easily be shared with other scientists, without the need to travel long distances; (5) sample sizes for research projects could be increased considerably by sharing resources between institutions; (6) some virtual data can show the inside of bones, not only the outside; (7) automatic osteometric measurements would be more accurate and far more repeatable with no inter- or intra-observer error; and, (8) automated systems could produce far more measurements that can be taken virtually rather than physically.

The full potential of ViSA will only be revealed when anthropologists start thinking outside the box and outside of the current, restricted ways in which osteometrics are performed. There is far more information in the bones that can only be unlocked digitally.

Virtual Skeletal Analysis, Osteometrics, 3D Bones

A48 Incorporating the "Black Bone" Magnetic Resonance Imaging (MRI) Technique: A Radiation-Free Alternative to Computed Tomography (CT) for Biological Profiling in the Living

Janamarie Truesdell, MSc, University of Oxford, School of Anthropology and Museum Ethnography, 51/53 Banbury Road, Oxford, Oxfordshire OX2 6PE, UNITED KINGDOM; Karen A. Eley, DPhil, University of Cambridge, Dept of Radiology, Addenbrooke's Hospital, Hills Road, Cambridge, Cambridgeshire CB2 0QQ, UNITED KINGDOM; Anthony McIntyre, BS, Oxford University Hospitals, The Churchill Hospital, Old Road, Headington, Oxford OX3 7LE, UNITED KINGDOM; and Nicholas Márquez-Grant, PhD, Cranfield University, Cranfield Forensic Institute, Defence Academy of the United Kingdom, Shrivenham SN6 8LA, UNITED KINGDOM*

After attending this presentation, attendees will be familiar with a novel, non-ionizing Magnetic Resonance (MR) technique with the potential to eliminate the need for CT in future biological profiling research.

This presentation will impact the forensic science community by introducing the radiation-free "Black Bone" MRI sequence, which, when 3D rendered, provides diagnostic image quality equivalent (for the purposes of age estimation) to that of CT scanning.

For forensic anthropologists, called upon for investigations involving both the living and the recently dead, the future does not lie in the past but in the present. To make the most appropriate profiling estimations, a constantly updated understanding of modern populations and how they change is of paramount importance; however, as reference collections, and he techniques and assumptions based upon them, become increasingly removed from the people of today, this becomes more and more difficult with each passing year. In order to remain knowledgeable about the populations that constitute the bulk of the anthropologist's casework, it is imperative that we begin to update our reference material as quickly and as comprehensively as possible. To do this, an intensified focus into medical imaging is required. Bone is optimally imaged by CT; however, due to ethical considerations regarding ionizing radiation exposure, imaging studies have been limited to patients already being examined for other purposes. This precludes the recruiting of volunteers for specific investigations such as the effect of substance abuse on aging from the fourth rib. For such a study, individual substances would have to be separated so as not to confuse results (smokers often drink and drinkers often smoke, so two groups — a smoking-only group and a drinking-only group — would have to be recruited to isolate these variables). This type of tailoring is currently impossible due to the restrictions surrounding CT, effectively stifling advancement in this area until an alternative can be found.

"Black Bone" MRI offers a potentially revolutionary solution, achieved through a novel approach, to overcome the notorious failures of routine MRI techniques in 3D bone imaging. Utilizing a gradient echo sequence with a low flip angle (optimized to 5°), short Repetition Times (TR=8.6ms) and Gradient Echo times (GE=4.2ms), "Black Bone" MRI enhances the soft tissue-bone interface by reducing the contrast of the surrounding soft tissues and medullary bone. This results in bone appearing densely black (hence "Black Bone") while the surrounding tissue remains a uniform gray, thus lending itself to 3D bone-rendering techniques.[1] "Black Bone" MRI has been utilized in a range of clinical settings, particularly within the head and neck, with successful 3D bone reconstruction. Recognizing the forensic potential of this technique, a small pilot study was focused upon reconstructing the pubic symphysis to investigate its applications for biological profiling.

Five patients undergoing multimodality (both MRI and CT) imaging of the pelvis for routine clinical care at Oxford's Churchill Hospital, United Kingdom, were recruited. "Black Bone" MRI images of the pubic symphysis were 3D rendered utilizing a range of image-processing techniques. Age estimation was performed on both the "Black Bone" MRI and CT images using the Suchey-Brooks method for aging the os pubis.[2] Results for both modalities were then compared and correlated with known age. In each case, "Black Bone" MRI proved an equally suitable medium for age estimation from the pubic symphysis.

In conclusion, this pilot study demonstrates the promising, immediately applicable advantages of the "Black Bone" MRI technique both in current forensic context and as a much-needed potential replacement for CT in future biological profiling research.

A49 DCP 2.0: Changes in Data Collection Procedures for Forensic Skeletal Material

Natalie R. Langley, PhD, Lincoln Memorial University, DeBusk College Osteopathic Med, 6965 Cumberland Gap Parkway, Harrogate, TN 37752; Lee Meadows Jantz, PhD, University of Tennessee, Dept of Anthropology, 250 S Stadium Hall, Knoxville, TN 37996-0720; Shauna McNulty, MA, University of Tennessee, 250 S Stadium Hall, Knoxville, TN 37996; Heli Maijanen, PhD, University of Oulu, PO Box 1000, Oulu 90014, FINLAND; Stephen D. Ousley, PhD, Dept of Anthropology/Archaeology, Mercyhurst University, 501 E 38th Street, Erie, PA 16546; and Richard Jantz, PhD, University of Tennessee, Dept of Anthropology, Knoxville, TN 37996-0720*

After attending this presentation, attendees will be aware of changes to skeletal measurements that interface with the FORDISC® software program. Attendees will be provided information about Data Collection Procedures for Forensic Skeletal Material 2.0 (DCP 2.0) and an accompanying online instructional video. Additionally, attendees will be surveyed about the need for continuing education in osteometric data collection.

This presentation will impact the forensic science community by informing practitioners and researchers about significant changes in osteometric data collection protocols related to the FORDISC® software and ongoing data collection efforts of the Forensic Data Bank. This information is imperative for forensic anthropologists who use the FORDISC® software in their forensic casework.

The foundations for changes in osteometric data were presented at the 2015 AAFS Annual Scientific Meeting (Abstract A84) and the preliminary results of research that is now complete. Briefly, the National Institute of Justice funded an effort to determine error rates associated with commonly used skeletal measurements and to evaluate alternatives for problematic measurements. Four observers took 78 standard (34 cranial and 44 postcranial) and 20 less-commonly used measurements on 50 skeletons from the University of Tennessee's William M. Bass Donated Collection. Each observer repeated the measurements on the 50 skeletons four times with a two-month time lapse between sessions. Relative Technical Error of Measurement (TEM), Scaled Error Index (SEI), and repeated measures Analysis of Variance (ANOVAs) with Tukey-Kramer post-hoc tests were used to assess the degree of inter-observer and intra-observer error for each measurement. Final results indicate that measures of maxima and minima are the most precise and repeatable measurements between and among observers. For example, biauricular breadth and bizygomatic breadth have relative TEM values of 0.054 and 0.0719, respectively. On the other hand, ischium and pubis length have respective TEM values of 36.52 and 41.06, respectively. SEI values showed that ischium and pubis length also have high intra-observer error rates. Repeated measures ANOVAs were used to determine measurements that were overall poor performers versus measurements that performed well with two or more observers (but not across the board). Inconsistent error rates between observers were indicative of problems with measurement definitions.

The final results of this research have brought about the following changes in osteometric data: (1) positionally dependent measurements of shaft diameters (i.e., sagittal, transverse, dorso-volar, anterior-posterior, etc.) have been abandoned for maxima and minima at midshaft for all long bones; (2) pubis and ischium length have been removed; (3) several measurements of epiphyses and/or articular surfaces have been added (e.g., maximum olecranon breadth, maximum radial head diameter, Anterior-Posterior (AP) diameter of S1, maximum glenoid cavity breadth); and, (4) landmark and measurement definitions have been clarified to facilitate higher precision and repeatability. Most definitions follow Howells and Martin and Knussmann; the latter was checked for translation accuracy.[1,2] Error rates for all measurements will be provided in the DCP 2.0 manual. The manual will be available in portable document format online and as a bound laboratory or field manual. In addition, an accompanying instructional online video will be made available to practitioners. Work is in progress to make the video available in English, Spanish, and French.

The DCP 2.0 is designed to be compatible with the FORDISC® software, as this software will become the primary means of collecting skeletal and osteometric data for research and development purposes. As such, the age estimation material in the DCP is being replaced with the transition analysis method. Materials have been provided to be incorporated into the DCP 2.0. Also, the new DCP will be versioned, like the associated FORDISC® software, to ensure that users are apprised of updates.

The information reported in this abstract does not represent the opinions of the National Institute of Justice.

Osteometric Data, Observer Error, FORDISC®

A50 Scanning Electron Microscopy/Energy Dispersive X-Ray (SEM/EDX): A Rapid Diagnostic Tool to Aid the Identification of Burnt Bone and Contested Cremains

Sarah Ellingham, MSc, Teesside University, School of Science and Engineering, Middlesbrough TS1 3BA, UNITED KINGDOM*

After attending this presentation, attendees will have a new appreciation for the value of SEM/EDX analysis for forensic anthropological investigations, particularly for the analysis of burnt remains.

This presentation will impact the forensic science community by detailing how the SEM/EDX can act as a quick and minimally destructive "fingerprinting" tool depicting a sample's elemental composition, thus aiding in the identification of burnt bone and contested cremains.

Having been recognized as a valuable tool to forensic anthropologists since the 1980s, the SEM has found application in a variety of different anthropological scenarios. SEM lends itself to the analysis of osseous material for numerous reasons; it has a superior resolution of 3D structures and a greater depth of field than light microscopy as well as being able to achieve higher magnification. When combined with EDX analysis, an insight into the gross elemental distribution of the sample can be directly related to a visual image of the assessed specimen. This makes it a useful screening tool when the osseous origin of a sample is in question, as was the case in the 2002 Tri State crematory incident. Although this technique has sporadically found application to burnt bone investigations, there has to date been no published, systematic study evaluating the change of EDX spectra over different exposure temperatures or whether the presence or absence of soft tissue during incineration plays a role.

Fresh sheep (O*vis aries*) ribs were divided into two experimental groups, defleshed and fleshed, with fleshed samples retaining the abdominal wall, circa 2cm subcutaneous fat and skin. Triplicates of each sample group were burned in an electric muffle furnace for 45 minutes at temperatures between 100°C and 1,100°C in 100°C increments. All remaining soft tissue was removed post burning. Samples were subsequently analyzed on a tabletop SEM, using a Backscatter Electron (BSE) detector, fitted with an EDX spectrometer for elemental analysis. Use of the variable pressure setting eliminated the need for sample coating. Morphological information was obtained using the BSE detector at 50x and 100x magnification. EDX measurements were taken at a live time of 50sec with a voltage of 20kV, mapping all detectable elements. For each experimental condition, nine EDX measurements were taken. Some trace elements such as Si and Al were removed from the spectra prior to analysis as they did not appear uniformly throughout samples and represented bones of one individual rather than elemental abundance, which was investigated in this study. A three-factor Analysis of Variance (ANOVA) was performed on the atomic percentage of each element in the sample.

Visual analyses of the external bone surface did not find any discernable differences between bones which were burnt with and without soft tissue present. Contrary to the findings of other researchers, curved "thumbnail" fractures were observed in defleshed as well as fleshed bones at high temperatures. Results of the 3-factor ANOVA showed that neither the exposure temperature nor whether the bones had been burned with or without soft tissue present made any significant influence on the bone's overall elemental makeup ($p>0.05$). The Calcium to Phosphorus (Ca/P) ratio, which several researchers refer to as the most characteristic elemental signature of bone, lay within the literature-quoted values of between 1.6 and 2.58 for both fleshed and defleshed bones when calculated using their weight percentage. There was no trend or pattern in these values at different temperatures.

This study has demonstrated that, even when faced with high temperatures, the overall gross elemental content and atomic percentage of elements in bone remains more or less stable, thus creating a unique "fingerprint" for osseous material, even after having been exposed to extreme conditions. The presence of soft tissue during burning does not change this. SEM/EDX has been found to be a valuable tool in the analysis of burnt bone and lends itself as a fast and minimally destructive method to identify burnt bone from other non-osseous material, which may otherwise appear morphologically similar.

SEM/EDX, Burnt Bone, Forensic Anthropology

A51 Reconstructing the Biological Profile of Cremated Human Remains

Anthony W. Hudson, BS, 9823 Utopia Drive, Apt 5203, Pensacola, FL 32514*

After attending this presentation, attendees will better understand the process of recreating pertinent biological profile information about cremated or burned human remains and which methods prove to be most successful.

This presentation will impact the forensic science community by providing results from a case study in an area with little previous or current research. This presentation will add to research being performed in the fields of forensic taphonomy and forensic anthropology by broadening the understanding of how human remains are affected by a burning episode and how those changes affect the process of identification.

Reconstructing the biological profile of burned/cremated remains can prove to be a difficult task due to the extensive damage that fire inflicts on bone, such as heat-induced fracturing/fragmentation, shrinkage, and shape alterations.[1] The relatively small amount of literature on the topic also serves to make the reconstruction process more difficult. Although there are some methods specific to identifying cremated remains, more standard methods may be required in a situation where remains have incurred damage from fire, whether accidentally or purposefully.

The basis of this research comes from a case study performed in 2013 utilizing an unprocessed commercial cremation, meaning that the remains were not pulverized after cremation, from Western Carolina University's skeletal collection. The remains were screened through a ¼" table screen and a series of nested screens in order to separate the largest and most identifiable pieces for use in reconstructing the biological profile. Approximately 25% of the remains could be readily identified as a certain element with distinguishing features present. These discernable elements provided the basis for the reconstruction process in this study. A multitude of identification methods were utilized throughout this study to assess aspects of biological profile such as sex, stature, and age. Techniques used to assess sex include cremation-specific weight studies performed by Warren and Maples, Bass and Jantz, and Van Deest et al., as well as the more standard Walker method of scoring the greater sciatic notch.[2-4] The Steele method of partial bone length reconstruction was utilized to predict stature, and the Suchey-Brooks and Todd methods utilizing the pubic symphysis to estimate age-at-death were also used.[5] These estimations were then compared to available personal data for the individual in order to assess the success of the various methods applied.

Application of the aforementioned methods proved to be partially successful for this case study, success being defined as having been able to apply a reconstruction technique and have an accurate estimation of biological profile returned. The results were deemed to be partially successful due to the cremation-specific sex estimations yielding various results (male, probably male, and ambiguous), while the greater sciatic notch clearly indicated male. Stature was estimated by applying the Steele method to a fragment of humerus, specifically the head and proximal shaft, yielding a stature between 5'8" and 6'. Living stature for this individual was unknown, so the accuracy of the stature estimation could not be determined. Age estimation based on pubic symphysis morphology produced a broad age range (27 years to 66 years), which was representative of the actual age at death for this individual (57 years).

In conclusion, it was discovered that it is possible to reconstruct, at least partially, the biological profile of human remains that have been burned, even at extreme temperatures. This is important to the fields of forensic anthropology and forensic taphonomy because it demonstrates that there are methods applicable to situations where burning has occurred, whether it is an attempt to conceal identity or a mass disaster.

Cremation, Taphonomy, Biological Profile

A52 Experimental Analysis of Burned Human Remains

Amanda Williams, MA, 2450 Lymbery Street, Apt 309, Reno, NV 89509; Elayne J. Pope, PhD, Tidewater OCME, 830 Southampton Avenue, Ste 100, Norfolk, VA 23510; and Marin A. Pilloud, PhD, University of Nevada, Reno/0096, 1664 N Virginia, Reno, NV 89557*

After attending this presentation, attendees will better understand the soft tissue and skeletal changes that occur to human remains as a result of a fire. Attendees will learn which variables are strongly correlated and can potentially be used to predict fire conditions.

This presentation will impact the forensic science community by describing the experimental analysis of burned human remains, while also highlighting important variables in fires that alter remains. This work will be the start of creating a new model to investigate fire-related damage to soft and skeletal tissue, which will prove important in aiding investigators who are building a legal case.

Currently, forensic anthropologists use the Crow-Glassman Scale (CGS) to analyze burned remains.[1] This scale progresses quickly from blistering to fragmentation in only five stages, without descriptions of times or temperatures that contribute to these changes. The scale can also be fairly subjective as it does not quantify surface area or percentage of body affected. As such, descriptions of burned bodies from pathologists and medical examiners are often inconsistent with those provided by forensic anthropologists.[2-5] The challenge at hand is to bridge the work between the various practitioners of the forensic sciences, all of whom may examine the same remains. Therefore, this pilot study employs a subset of data that seeks to develop a method more applicable to remains encountered in fires. This initial study employs the CGS as a first step in analysis and identifies variables that are significant in creating the conditions observed. The next step of this study will be to employ a larger dataset with additional variables to develop a more detailed descriptive model of burned human remains.

The initial study involves data collected in 2015. Observational experiments involved the burning of six donated human cadavers as part of the San Luis Obispo Fire Investigation Strike Team training course. Three cadavers were placed in vehicle fires and the other three in structural fires. All physical alterations to both soft and skeletal tissues were documented with digital photography and thermocouples within the fire environment. The visual assessment of the burned bodies was guided by the existing CGS and supplemented by additional descriptions of time and temperatures. Skin splits, subcutaneous fat exposure, muscle exposure, and presence or absence of soft tissue color banding were among the soft tissue variables recorded for each individual. Skeletal color banding, percent fragmented, and percent charring were among the skeletal changes recorded.

Individuals exhibited varying degrees of heat-related damage. The physical alterations were found to differ depending on fire environment, temperature, duration, and location of remains within each context. A majority of the remains from the car fires remained intact, with limited soft tissue loss and bone exposure, consistent with a CGS score of two; however, one individual exhibited calcination on the skull, upper and lower limbs, hands, and feet, which was absent in the other individuals, and is consistent with a CGS score of five. This individual also exhibited heat-related fracturing on both upper and lower limbs, a feature also absent in the other sets of remains. The variability in heat-related damage can be explained by this individual's placement in the trunk, longer exposure to heat, and increased temperatures.

Remains from the structural fires exhibited partial soft tissue loss and soft tissue color banding, which was concentrated at the lower and upper limbs, feet, and hands, consistent with a CGS score of two. None of the individuals in the structure fires exhibited bone exposure or fragmentation as seen with the car fire remains. The structure fire remains also exhibited a larger percentage of soft tissue color banding than the car fire remains. The variability found between vehicular and structural fires is due to variations in the type of environment, followed by the duration and temperatures of exposure.

Overall, the six individuals in this study demonstrate variability in heat-related damage. The initial results demonstrate there are differences between type of fire environment and duration, illustrating the possibility of modeling heat-related conditions. As data collection progresses, a more robust model can be created to predict fire conditions based on damage to soft and skeletal tissues.

Burned Human Remains, Crow-Glassman Scale, Forensic Anthropology

A53 Patterns of Ossification in Macerated Thyroid Cartilages: Implications for Age and Sex Determination

Katelyn L. Bolhofner, MA, Arizona State University, 900 S Cady Mall, Tempe, AZ 85287; and Laura C. Fulginiti, PhD, Forensic Science Center, 701 W Jefferson, Phoenix, AZ 85007*

After attending this presentation, attendees will be aware that the degree of ossification of the thyroid cartilage should not be used as an indicator in age-at-death assessment.

This presentation will impact the forensic science community by eliminating a commonly used indicator of age at death and by introducing a sex-specific pattern of ossification in the thyroid cartilage.

The ossification process of the thyroid cartilage has been researched extensively using radiographs and Computed Tomography (CT) scans.[1-6] This research has attempted to correlate age at death with the pattern of ossification, but the results are conflicting. Some suggest there is a standard progression that can be sorted into phases useful in age estimation, while others have found little correlation between ossification and age at death. Despite these conflicting results, ossification of the thyroid cartilage continues to be used as an indicator of advanced age. By examining the bone in these cases, it has been demonstrated that there is no correlation with age and no uniform pattern of ossification. Rather, it was found that there does appear to be a recognizable difference in pattern of ossification between the sexes.

This pilot study examined 32 ossified thyroid cartilages removed at autopsy. The sample included 20 males and 12 females that ranged in age from 25 years to 79 years. The samples were collected from modern forensic cases between 2005 and 2015 at the Maricopa County Office of the Medical Examiner and macerated according to standard protocols. Male and female samples were separated and the thyroid cartilages were scored using standard scoring techniques. The published phases were discordant with observed patterns of ossification in this sample, so photographs of the anterior view of the thyroid cartilages were taken and ordered by degree of ossification. Known age at death was then re-associated with the samples.

No statistically significant correlation between degree of ossification and age-at-death was found in either males or females (Spearman's rank-order: male: ρ=0.057, p=0.813, α=0.05 female: ρ=0.224, p=0.484, α=0.05). The highest degree of ossification was observed in a 31-year-old male and one of the least ossified thyroid cartilages was observed in a 79-year-old male. None of the thyroid cartilages from the female samples was as well ossified as those from the male samples. A statistically significant difference in the pattern of ossification was observed between males and females (χ2=8.5, p=0.00349, α=0.05), specifically in the ossification of the superior horns (cornua). Six of 20 males (30%) and 10 of 12 females (80%) exhibit ossification of the superior horns. This element appears to be the last portion of the cartilage to ossify in males, but appears early in the ossification process in females.

The majority of research on thyroid cartilage ossification has been conducted using non-invasive techniques, particularly radiography. Review of this literature demonstrates the difficulty in using these techniques to investigate the cartilage. For example, errors were published in two studies: the first indicates structures in a radiograph that are mislabeled as the thyroid cartilage, the second submits an artistic rendition of the ossified cartilage that is presented upside down.[7-8] Further, in this study, comparison of the digital postmortem radiographs obtained at autopsy to the macerated samples demonstrates that ossification is difficult to appreciate in a radiograph.

The results of this pilot study do not support any correlation between age at death and degree of ossification of the thyroid cartilage. The common perception that the presence of an ossified thyroid cartilage denotes very advanced age is patently false. Practitioners should not rely on ossified thyroid cartilage in any way during an age-at-death assessment. Further, this research demonstrates a significant difference between the pattern of ossification observed in males from that seen in females, suggesting that there may be implications for the use of thyroid cartilage ossification in sex estimation. This difference between the sexes is supported by recent immunohistochemical research that demonstrates sex-specific differences in cartilage mineralization of the laryngeal structures.[9-10] While the results of this pilot study appear to have important implications for skeletal analysis, an increase in sample size should strengthen the findings presented here.

Thyroid Cartilage, Ossification Patterns, Sex Determination

A54 Age Estimation of Adolescent and Post-Adolescent Children Via Radiographs of the Shoulder

Maureen Schaefer, PhD, Michigan State University, Division of Human Anatomy, E Fee Hall, 965 Fee Road, East Lansing, MI 48824-1316; and Gerald Aben, MD, Michigan State University, Radiology Bldg, 846 Service Road, Rm 184, East Lansing, MI 48824*

After attending this presentation, attendees will better understand the ages at which specific developmental milestones occur in regard to three of the epiphyses surrounding the shoulder. The radiographic data provided within the presentation can then be utilized to estimate the age of living or deceased children. Insight will also be gained into developmental processes that can aid in the determination of whether an individual is likely to be older or younger than two common threshold ages (16 years or 18 years).

This presentation will impact the forensic science community by providing age documentation of a joint region whose development has been traditionally understudied via radiographic means.

Age estimation using radiographic data is becoming increasingly important due to a surge in requests to estimate the age of living children. While numerous radiographic studies have been conducted on the development of the hand, medial clavicle, and iliac crest, a paucity of data exists in the recording of radiographic changes occurring at the shoulder. This presentation fills that void by providing the appearance and/or union times of the epiphyses of the angle/apex of the coracoid process, acromion process, and proximal humerus.

Developmental processes occurring at the three epiphyses were noted utilizing multiple views of shoulder radiographs from 264 males and 189 females between the ages of 10 years and 21 years of age. Images were obtained via two sources, including the Michigan State University's Clinical Center and Query Patricia, an online juvenile radiographic database developed by Mercyhurst University. Each epiphysis was assigned a unique phasing system based on the extent to which developmental processes could be visualized radiographically. Progressive union of the proximal humerus was the least challenging of the elements to interpret and therefore received the most robust phasing system, which included four stages: Phase 1=open union; Phase 2=active union; Phase 3=an unfused notch remains; and, Phase 4=complete union. Appearance times of the proximal humerus were unable to be documented due to the age limitations of the sample, which only included preadolescent and adolescent children. The epiphyses of the coracoid and acromion processes presented a greater interpretive challenge and therefore were assigned phasing systems that were less descriptive; however, the late appearance times of both these epiphyses did permit the inclusion of this event within the phasing system. The acromion process was assigned a three-phase scoring system: Phase 0=epiphysis not present; Phase 1=present and open or fusing; and, Phase 4=complete union. The angle and apex epiphyses of the coracoid process were the most difficult to interpret and therefore information was only recorded if the epiphysis was present and not completely fused.

Observations were recorded for each of the three elements and their age/phase distributions provided. A number of developmental processes were observed to always occur before the age of 16 years or 18 years. These results suggest that the shoulder region may be of particular value when evaluating the likely direction of an individual's age in relation to either of these two common threshold values.

Shoulder Development, Age Estimation, Developmental Osteology

A55 A Grading System to Assess the Sex and Parity Status for the Preauricular Sulcus

Sarah E. Canty, PhD, Liverpool John Moores University, James Parsons Bldg, Byrom Street, Liverpool, Wiltshire L3 3AF, UNITED KINGDOM; Matteo Borrini, PhD*, Liverpool John Moores University, RCEAP-School of Natural Science & Psych, Byrom Street, Liverpool L3 3AF, UNITED KINGDOM; Constantine Eliopoulos, PhD, Liverpool John Moores Univ, School of Nat Science & Psych, James Parsons Bldg, Byrom Street, Liverpool L3 3AF, UNITED KINGDOM; and Silvia Gonzalez, PhD, Liverpool John Moores University, Byrom Street, Liverpool, Merseyside L3 3AF, UNITED KINGDOM*

After attending this presentation, attendees will have a better understanding of the sexual dimorphic variability of the preauricular sulcus in human adult os coxae.

This presentation will impact the forensic science community by providing a grading system for the preauricular sulcus as a sexually dimorphic trait and a musculoskeletal stress marker.

Forensic anthropologists, anatomists, and clinicians have long suggested that pregnancy and parturition may leave a "scar" on the skeleton, especially the os coxae; however, there has been much debate and no clear method for examination has been established. The preauricular sulcus or groove is found on the os coxae between the auricular surface and the greater sciatic notch. It is the site of the attachment for the anterior sacroiliac ligament. During pregnancy, this ligament is loosened in order to widen the birth canal in preparation for parturition; these changes cause remodeling of the bone that can be observed.

The goal of this research was to examine the effects of sexual dimorphism, pregnancy, and parturition on the preauricular sulcus.

Two English medieval skeletal collections were examined in this research, the Poulton collection (sample size=59) and the St. Owens Church Gloucester collection (sample size=108) both housed at Liverpool John Moores University. The skeletal material has been aged and sexed using multiple established methods and compared through inter-observer error with the estimations produced by other forensic anthropologists.

A grading system was designed to examine the different types of sulcus, which was evaluated to range from Grade 0 to Grade 4: (1) Grade 0 — no preauricular sulcus present; (2) Grade 1 — a preauricular sulcus that is shallow and the floor of the sulcus has a uniform depth; there are no pits or grooves and the edges are often undefined. This grade is often scarcely visible, which can make the measurements difficult, as there are usually no definite edges; (3) Grade 2 — a preauricular sulcus whose floor has a slightly uneven depth and is not completely smooth. There should only be a small change in depth; however, a preauricular sulcus with more than one pit of different depths would instead be classified as a Grade 3; (4) Grade 3 — this Grade, although similar to Grade 2, differs as the floor of the sulcu has multiple varying depths and will have more than one pit. Grade 3 has a more defined edge than Grades 1 and 2; and, (5) Grade 4 — a preauricular sulcus whose floor has a very inconsistent depth; it will have multiple deep pits or channels through the sulcus. The surface of the sulcus will appear rough and is very easy to observe on the bone. Unlike Grade 1 preauricular sulcus, it would be difficult to overlook. Grade 4 typically looks like a deep channel in the bone.

For this research, each os coxae was individually graded. In addition, the maximum length and width of the sulcus was recorded, along with the sex of the individual. The data from the two collections were combined. The results showed a significant difference in the occurrence rates of the preauricular sulcus in males and females, demonstrating the value of this characteristic as a sexual indicator. A preauricular sulcus was present in 91.3% of females and not present in only 8.8%, while for males, preauricular sulci was only present in 39.5% of cases and are not present in the majority, 60.5%. The research also suggests that pregnancy and parturition does leave a mark on the sulcus. No Grades 3 or 4 sulci, which were suggested to be indicators of pregnancy and parturition, were found in males. They were only found in females that could have been parous, as 47.5% of females had Grade 3 and 8.8% had Grade 4. To verify this method, the proposed scoring system will be tested in the future on additional skeletal collections

According to the trend of modern forensic sciences, which are looking for valid and reliable methods, this study proposes a new scoring system to evaluate the morphology of the preauricular sulcus in relation to sex and possible parity status.

Sexual Dimorphism, Preauricular Sulcus, Pregnancy

A56 Bioarchaeological Investigations Discovered Intraindividual Bilateral Ossification Differences of the Medial Clavicle — Implications for Age Estimation of the Living

Fabian Kanz, PhD, Medical University of Vienna, Department of Forensic Medicine, Sensengasse 2, Vienna, YT 1090; Philipp Konermann, MD, Department of Forensic Medicine, Medical University of Vienna, Sensengasse 2, Vienna 1090; and Sandra Lösch, PhD, University of Bern, Institute of Forensic Medicine, Dept of Physical Anthropology, Sulgenauweg 40, Bern 3007, SWITZERLAND*

After attending this presentation, attendees will: (1) understand how bioarchaeological studies on human remains can support research in forensic anthropology; and, (2) be aware of possible ossification differences of the left and right clavicle and the implications for the procedure of age estimation of the living.

This presentation will impact the forensic science community in terms of knowledge and competence to modify the procedure of age estimation of the living by considering the development of the medial epiphysis of both clavicles, which will enhance the accuracy of the method.

Age determination in the living is put into practice both in criminal and asylum law. Within the standardized multifactorial examination by experts, the evaluation of the stage of ossification of the medial clavicle is of crucial importance. The complete fusion of the epiphysis is believed to be closely related to the time at which the age of legal majority is reached in many countries. In recent times, serious doubts arose concerning the assumption that bilateral ossification differences of the medial clavicle are negligible for age determination.[1] Asymmetric workload an individual is exposed to during his/her skeletal growth period might be responsible for differences in the ossification progress of the clavicles. A Medieval and an Early Modern Age population were chosen for investigation, assuming that workload conditions in historic times may better reflect the living conditions (hard manual labor) in countries from which the majority of the individuals subjected to age estimation procedures (asylum seeker and immigrants) in Austria and Switzerland originate.

The investigated individuals were collected during the archaeological excavation of a cemetery in St. Pölten in Lower Austria. Both clavicles of 70 females, 88 males, and 42 individuals with morphologically indeterminable sex were macroscopically investigated twice. Each clavicle was rated on the basis of the five-stage classification provided by Schmeling et al.[2] Definition of the five-stages (I–V) are: Stage I — non-ossified epiphysis; Stage II — discernible ossification center; Stage III — partial fusion; Stage IV — total fusion but epiphyseal scare still visible; and, Stage V — total fusion and epiphyseal scar no longer visible. Relative differences of the two clavicles in each ossification stage as well as inter-observer error as Overall Percentage Agreement (OPA) and Kappa value (κ) of the two independent observations were calculated. The χ^2 test was performed to investigate significant dissimilarities of side differences observed in the investigated ossification stages.

The distribution of the 200 investigated clavicle pairs was found to be nearly equal in the defined five stages and maximum side differences did not exceed one stage. In Stage I, 14.3% of the individuals showed side differences, 15.6% in Stage II, 50.0% in Stage III, 15.0% in Stage IV, and 13.5% in Stage V. For the individuals with known sex, the females (24.7%) tend to have stage differences more often than males (14.7%). The differences were found to be most pronounced in Stage III (females=61.5% and males=33.3%).

The inter-observer error turned out to be acceptable as evidenced by an OPA of 88.0% and the κ-value=0.83. The χ^2 test indicated significant differences (p=0.001, α=0.05) in the ossification stages only when Stage III was included. If Stage III was excluded, no significant differences between the Stages I, II, IV, and V could be found (p=0.995).

Since Stage III is most important for the decision of if an individual has already reached the age of legal majority or not, and the greatest bilateral differences were found in this stage. It is strictly recommended that both the left and right clavicle should be investigated during the age estimation procedure. In case of discrepancy, the clavicle expressing the ossification stage which promotes the interest of the investigated person should be favored in terms of "*in dubio pro minore*."

Bioarchaeology, Medial Clavicle, Bilateral Ossification

A57 The Use of the Sustentaculum Tali in Estimating Sex

Christine Bailey, BA, University of Tennessee, Knoxville, 250 S Stadium Hall, Knoxville, TN 37996; Kristen A. Broehl, BA*, California State University, Chico, 400 W First Street, Chico, CA 95929; Amy Z. Mundorff, PhD, University of Tennessee, Dept of Anthropology, 250 S Stadium Hall, Knoxville, TN 37996; and Renee C. Kosalka, MA, 32 Thirty-Third Street, Toronto, ON M8W 3H1, CANADA*

After attending this presentation, attendees will better understand how the Sustentaculum Tali (ST) may be used in estimating sex in decomposed and skeletonized human remains. Attendees will also be introduced to new osteological measurements developed for this study.

This presentation will impact the forensic science community by providing an alternate method for metrically sexing skeletal remains. The sexually dimorphic parameters used in this research will be valuable in conjunction with other sexing techniques.

Sex estimation is a crucial component of the biological profile of unidentified skeletal remains; however, conventional methods of sex estimation are not always feasible when certain sexually dimorphic elements are missing or fragmented. Therefore, it is important to develop additional methods for sex estimation using non-traditional skeletal elements. Forensic practitioners have noted that calcanei are often recovered intact due to their density and protection within shoes and may, therefore, be a viable data source.[1,2] Previous research has also shown the calcaneus to be a sexually dimorphic skeletal element. These studies have considered the calcaneus as a whole but have not focused on dimensions of the ST in particular. Since the ST is a point of articulation between the calcaneus and talus, both sexually dimorphic bones, and existing sexually dimorphic measurements of the calcaneus encompass the ST, it is hypothesized that measurements of the ST will be useful in discriminating male and female calcanei.

The study was comprised of calcanei from 40 individuals, 20 male and 20 female, from the William M. Bass Donated Skeletal Collection at the University of Tennessee, Knoxville. Two researchers independently measured four parameters of the ST: Length (STL), Width (STW), Height (STH), and medial talar Facet length (STF). Measurements in this study were defined and each researcher measured the 40 calcanei three times to assess intra-observer error. A third researcher, uninvolved in developing the measurements, also measured the 40 calcanei to assess inter-observer error and the reliability of the definitions. Discriminant functions were derived using the Statistical Package for the Social Sciences (SPSS) v.21, and an additional sample of 28 calcanei was used to test the accuracy of the functions.

The results show sexual dimorphism for three measurements: STL (p=.000), STW (p=.050), and STF (p=.000). There was no significant difference between males and females for STH. Univariate discriminant analyses were run for the three sexually dimorphic dimensions, resulting in accuracies ranging from 60.0% to 77.5%. Direct discriminant function analyses were run using various combinations of the four variables, correctly classifying 72.5% to 75.0% of the sample. The test sample was classified using the discriminant functions derived from the original sample. The univariate functions accurately sexed 71.4% to 75.0% of the test sample, and the multivariate functions accurately sexed 75.0% to 85.7%.

The results of this study support the hypothesis that dimensions of the ST are useful for sex estimation. The measurements STL and STF had accuracies comparable to previous studies using the calcaneus. The results of this study are particularly important in cases where fragmented calcanei prevent the use of other measurements.

Forensic Anthropology, Sex Estimation, Calcaneus

A58 The Roaming Arm: A Literal Outlier

Shana Ott, Metropolitan State Univ Denver, Chemistry Dept, PO Box 173362, Campus Box 52, Denver, CO 80217-3362; and Gary T. Scott, MA*, Metropolitan State University of Denver, Dept of Anthropology and Sociology, 1201 5th Street, Campus Box 28, Denver, CO 80204*

After attending this presentation, attendees will better understand animal scattering of human remains, distances of transport, and how this may affect search and recovery planning.

This presentation will impact the forensic science community by presenting a case study of a suspected animal transport of a human arm for more than one mile, which exceeds previously documented scatter distances.

Per Haglund, regarding the taphonomy of human remains, dog and coyote scavenging results in consumption, disarticulation, modification of bone, and scattering of remains.[1] Having knowledge of the fauna, flora, seasonality, clothing, postmortem interval, topography, and environment could all impact the distance that human remains are scattered.[2-4] This information is critically important when disarticulated human remains are located in an outdoor setting and recovery is required. In forensic contexts, following the initial discovery and reporting of human remains, it becomes the responsibility and jurisdiction of law enforcement, coroners, and medical examiners to search for any missing remains. Search parameters often are influenced by budgetary constraints; therefore, data on scatter patterns and distances will assist in pre-search planning.

On June 2, 2015, a group of hikers discovered a desiccated, articulated, skeletonized left arm (scapula, clavicle, humerus, radius, ulna, carpals, metacarpals, and most phalanges). These remains were reported to and recovered by the Park County Coroner and Park County Sheriff's Department. A subsequent search in the area by law enforcement, Colorado Forensic Canines, Search and Rescue Dogs of Colorado, Park County Search and Rescue, and Metropolitan State University of Denver Human Identification Laboratory personnel did not result in finding additional human remains.

On July 8, 2015, a hiker went off trail in Park County, CO, and discovered a desiccated, mostly articulated human skeleton. The left arm was missing. The body was exposed and on the ground surface. Underwear, jeans, socks, and boots, remained on the body; a shirt and jacket were nearby.

The body had a rope around the neck and presented as a suicide; body positioning and vegetation discoloration were all consistent in indicating that the remains were at their original deposition site. While it was suspected that the body and the previously discovered arm were from a single individual, the cases were processed separately. Subsequently, the body was positively identified as those of an 18-year-old male. The individual had been reported missing on October 22, 2014, his car was discovered at a Trailhead in Park County, CO, on October 24, 2014, and a suicide note was found inside the car; this initiated a search, but the individual was not found.

Subsequently, the arm was matched to the body (no overlapping remains, the bones were consistent in size, morphology, and degree of decomposition) and both displayed minimal carnivore gnawing and chewing.

When comparing the Global Positioning Coordinates of the body and left arm, it was found that they were separated by a straight-line distance of more than one mile (1,900 meters), which significantly exceeds the documented distances within the literature. Haglund states that, following scavenging, most skeletal elements are recovered within a 100-meter radius of where the body was found.[1] Haglund and others have documented maximum transport of remains at distances of 402, 291, 200, and fewer meters.[5-7]

A number of factors can play a role in the scatter of human remains including mammals, plants, topography, climate, clothing, and postmortem interval, among others. The remains were located 2,500 meters (8,200 feet) above sea level, in steep terrain with a mix of conifer trees, shrubs, and boulders, exposed to temperatures ranging from -23°C to 24°C (-10°F to 75° F) and monthly snowfall amounts ranged from 8-86 centimeters (3-34 inches) during the months of November 2014 through May 2015. It is important to document these variables to assist with subsequent search planning and briefings.

Scavenging, Scattered Remains, Searches

A59 No Fly Zone: Decomposition in the Absence of Insects

Michael S. Woolf, BS, Virginia Commonwealth University, 6732 Hopton Court, Richmond, VA 23226; Tal Simmons, PhD*, Virginia Commonwealth University, Dept of Forensic Science, 1015 Floyd Avenue, Richmond, VA 23284; and Baneshwar Singh, PhD, Virginia Commonwealth University, Dept of Forensic Science, 1015 Floyd Avenue, Rm 2015, Richmond, VA 23284*

After attending this presentation, attendees will better understand how insects drive the decomposition process when all other variables are held constant.

This presentation will impact the forensic science community by providing results from a controlled experiment which compared decomposition rate and pattern between insect-access and insect-exclusion groups of pigs. These results are compared to previously published work using different animal models.

Although Accumulated Degree Days (ADD) provide a framework for comparing decomposition in disparate regions, temperature is not the sole impetus of decomposition; as many have noted, insects are one of the primary drivers of biomass removal leading to skeletonization. Previously published work compared the process of decomposition in the presence and absence of insects using a combination of previously published, experimental, and retrospective data; the results indicated that the absence of insects (whether achieved through deposition indoors, in burial, or in water) slowed the rate of decomposition in the same manner and regardless of weight.[1]

In this experiment, 12 pigs (*Sus scrofa*) weighing 22kg-32kg, killed by a .22 caliber bullet to the head, were placed in an open field at the Virginia State Police Training Center in Hanover, VA, on June 10, 2015. All pigs were placed individually in scavenger-proof wire cages, 10m apart. Six cages were also enclosed within an outer tent constructed of Polyvinyl Chloride (PVC) pipe overlaid with fine mesh netting to exclude insects. These tents were weighted with sandbags along the bottom edge and could be entered through a zippered opening in one side, the bottom of which was covered with a flap and weighted with another sandbag. To mimic the partial shade provided by the insect exclusion nets, shade cloth was placed on the top of each insect access cage. Temperature onsite was recorded hourly by a datalogger attached to one of the cages. Pigs were observed daily for the first ten days (to 296 ADD), on alternate days for the succeeding two weeks (to 575 ADD), then once a week for two more weeks (to 903 ADD) when the insect-accessed pigs had reached Total Body Score (TBS) of 26-30 on the revised 32-point scale, indicating >50% bone exposure, with mummification and some areas exhibiting greasy bone only.[2] Insects were collected and identified at each visit.

Adult flies from family Calliphoridae (*Phormia regina*, *Lucillia spp.*, and *Cochliomyia macellaria*) and beetles from families Silphidae (*Necrophila americana*, *Necrodes surinamensis*, and *Oiceoptoma novaboracense*) and Staphylinidae (*Creophilus maxillosu*s) were observed in large numbers during early decomposition stages (fresh and bloat). Egg masses and larvae were also noted within 24hrs (27 ADD). In addition to those aforementioned species, beetles from family Cleridae (*Necrobia rufipes*) were noted during later decomposition stages (active decay, advanced decay, and dry). Overall, *Phormia regina* and *Creophilus maxillosus* were the most prevalent insect species throughout this study. Peak maggot masses migration occurred between days 7-8 (237 to 267 ADD).

Preliminary linear regression indicates a strong, positive linear relationship between ADD and TBS for the exclusion and access groups with R^2 values of 0.9118 and 0.9118, respectively. Slopes and intercepts for both estimated regression lines are different. The equation for the insect exclusion group is TBS=-15.6760+11.0134 ($\log_{10}$ADD) while the equation for insect access group is TBS=-30.9506+20.9872 ($\log_{10}$ADD). Analysis of Variance (ANOVA) ($p \leq$6.193e-13) and Analysis of Covariance (ANCOVA) ($p \leq$2.2e-16) indicate that the difference in group means and the effect of ADD on TBS are statistically significant. Linear mixed-effects modeling will also be used to assess TBS as the response variable and group assignment (insect access or exclusion) as a random variable.

In conclusion, this study provides further evidence that necrotizing insects function as primary colonizers that accelerate decomposition with a strong, positive linear relationship to ADD. Additionally, this study provides much-needed geographical data for the development of model-based methods for estimation of human Postmortem Interval (PMI).[2]

Taphonomy, Insects, Decomposition

A60 White-Tailed Deer as a Taphonomic Agent: Photographic Documentation of White-Tailed Deer Gnawing on Human Bone

Daniel J. Wescott, PhD, Texas State University, Dept of Anthropology, 601 University Drive, San Marcos, TX 78666-4684; Lauren Alyssa Meckel, BS*, Texas State University, 1509 Marlton Street, San Marcos, TX 78666; Chloe P. McDaneld, 125 Amberwood Cove, Kyle, TX 78640; Michelle D. Hamilton, PhD, Texas State University, Dept of Anthropology, 601 University Drive, San Marcos, TX 78666; Sophia Mavroudas, MA, Texas State University, 601 University Drive, ELA 232, San Marcos, TX 78666; and Kate Spradley, PhD, Texas State University, Dept of Anthropology, 601 University Drive, San Marcos, TX 78666*

After attending this presentation, attendees will better understand the damage caused to bone by white-tailed deer gnawing.

This presentation will impact the forensic science community by providing photographic documentation of white-tailed deer gnawing on human bone and therefore acting as a taphonomic agent.

While most forensic anthropologists and taphonomists are aware that carnivores and rodents gnaw on and consume human bones, the fact that cervids and other ruminant species also chew on bone is not as widely recognized. Cervids (e.g., deer, elk, moose) gnawing on bone has been reported in the taphonomic and zooarchaeological literature, but there is no known report of cervids altering human remains.[1-4] This study reports on the first known documented case of white-tailed deer gnawing on human skeletal remains and discusses distinguishing features of ungulate gnawing and the reasons for this behavior.

The Forensic Anthropology Center at Texas State University (FACTS) accepts human donations for taphonomic research. As part of an ongoing research project to document scavenging activities on naturally decomposing human remains, a motion-sensitive camera was place approximately 4.5 meters from an uncaged human body.[5] The donated body was placed in a small wooded area at the Forensic Anthropology Research Facility (FARF) in July 2014. The body was initially scavenged by vultures that removed much of the soft tissue, leaving a mostly articulated skeleton and large pieces of desiccated skin. At approximately 190 days postmortem, a motion-sensitive cameras captured multiple images of a young deer with a human rib bone in its mouth on two different occasions.

Upon discovery of the photographs, the skeletal remains were investigated more closely. The two ribs gnawed by the deer had been disarticulated from the vertebral column and moved less than one meter from the articulated trunk. The ribs exhibited splintering of the sternal ends that has been characterized as "forking," but no obvious signs of tooth depressions, punctures, or grooves. The forking is characteristic of ungulate damage and was caused by the deer holding the sternal end in its mouth parallel to the tooth row and rubbing its teeth against the bone.[1]

Deer and other cervids most likely gnaw on or consume bone to obtain phosphorus, calcium, and other minerals absent from their vegetarian diet, especially in the winter, and prefer relatively fresh bone. In addition to forking, cervid damage to bone can include tooth impressions, grooves, and punctures, which are also common in bone gnawed on by carnivores and rodents; however, the damage caused by deer and other ruminant species can be distinguished from modifications caused carnivores and rodents.

While cervids do not greatly contribute to the scavenging guild, they should not be overlooked as a possible taphonomic agent in the modification of human remains in medicolegal death investigations. In regions with large cervid populations, forensic scientists should be aware of the potential damage that can be caused to bone by cervid species.

Osteophagia, Taphonomy, Bone Modification

A61 Examining the Persistence of Human DNA in Soil During Cadaver Decomposition

Alexandra L. Emmons, MA, University of Tennessee, 2831 Island Home Avenue, Knoxville, TN 37920; Jennifer DeBruyn, PhD; Amy Z. Mundorff, PhD, University of Tennessee, Dept of Anthropology, 250 S Stadium Hall, Knoxville, TN 37996; Kelly L. Cobaugh, MS, University of Tennessee, 2506 E.J. Chapman Drive, Knoxville, TN 37996; and Graciela S. Cabana, PhD, University of Tennessee, 250 S Stadium Hall, Knoxville, TN 37996-0720*

After attending this presentation, attendees will gain a more thorough understanding of the persistence of human DNA in the soil during human cadaveric decomposition.

This presentation will impact the forensic science community by complementing existing information concerning taphonomic changes in the soil environment during human decomposition. The results of this project will progress the understanding of the persistence of human DNA in soil, thereby expanding upon the current understanding of the interplay between chemical, physical, and biological processes occurring in the soil in concert with human decomposition.

The majority of experimental work involving human decomposition has focused on aboveground processes, ignoring the potential impact imposed on the underlying soil. Though recent decades have seen a marked increase in research of this type, including the fate of certain cadaveric biological correlates once they enter the soil, the fate of another important biological correlate in grave soil — human DNA — has been relatively understudied.[1-10] This study sought to redress this gap in existing knowledge by assessing the persistence (i.e., presence or absence) of human nuclear and mitochondrial DNA (mtDNA) and evaluating the quantity of recovered DNA from soil over the course of decomposition of four human cadavers placed at the University of Tennessee's Anthropological Research Facility.

To test hypotheses that both human nuclear and mtDNA would be recoverable from the soil environment and that the quantity of DNA would be greatest during active and advanced decay stages of decomposition, samples were assessed using end-point and real-time quantitative PCR (qPCR). Cadaver DNA from soil samples was verified by comparing sequences from the human mtDNA control region (HVI and HVII) between cadaver blood samples and a subset of soil samples taken from below each cadaver following the initiation of decomposition.

Human nuclear DNA was largely unrecoverable from the soil throughout decomposition, while cadaver mitochondrial DNA was detectable throughout all decomposition stages. MtDNA copy number increased as decomposition progressed, peaked during active decay (Max. Value=$1.9X10^6$ copies gdw^{-1}), and declined throughout the remainder of decomposition, reaching a minimum value of $1.4X10^4$ copies gdw^{-1}. When tested against additional variables including time (measured in Cumulative Degree Hours (CDH)) and soil chemistry, mtDNA copy number showed a positive correlation with CDH (r_s=0.420, p=0.041), Total Organic Carbon (TOC) (r_s=0.418, p=0.042), and Total extractable Nitrogen (TN) (r_s=0.569, p=0.004).

In conclusion, human mtDNA can be recovered from soil and is of a high enough quality to be used for exclusionary purposes during identification efforts.

Soil Taphonomy, Human DNA, Identification

A62 Using the Geographic Information System (GIS) to Distinguish Between Human and Non-Human Cranial Bone Fragments

Brigida Corrieri, MSc, Cranfield University, Cranfield Forensic Institute, Defence Academy of the United Kingdom, Shrivenham, Oxfordshire SN6 8LA, UNITED KINGDOM; Nicholas Márquez-Grant, PhD*, Cranfield University, Cranfield Forensic Institute, Defence Academy of the United Kingdom, Shrivenham SN6 8LA, UNITED KINGDOM; Jessica Bolton, MSc, Cranfield University, Cranfield Forensic Institute, Defence Academy of the United Kingdom, Shrivenham SN6 8LA, UNITED KINGDOM; and Roland Wessling, MSc, Cranfield Univeristy, Cranfield Forensic Institute, Shrivenham, Oxfordshire SN6 8LA, UNITED KINGDOM*

After attending this presentation, attendees will be aware of the utility of GIS in the distinction between human and non-human cranial fragments. The method presented shows an innovative application of the geographical system, which was used to measure the sutures pattern and the bone curvature of human and non-human skulls, with the goal of creating a database that can be used for a quick identification of small cranial fragments.

This presentation will impact the forensic science community by demonstrating that GIS, a system usually used to manage geographic data, can be a useful tool for the differentiation between human and non-human fragmented cranial bones, with the advantage of being a cheap and non-destructive method that can speed up the identification process.

Cranial bone fragments can be found isolated in forensic contexts, such as fatal fires and mass disasters. In some instances, when bone fragments are present, police will call upon the anthropologist to understand if they are human or not. Whether the bone is confidently assigned as human or not will have repercussions for the investigation and will affect cost and time spent in the investigative process. Indeed, some small cranial bone fragments can present a real challenge for anthropologists and as many methods as possible must be used in order to establish their human or non-human origin.

Human and non-human crania, both juvenile and adult, were employed for the GIS measurements. The animal species chosen for the study were fox, cattle, and sheep. The skulls of these animals may be problematic if found fragmented, because they share some characteristics with human ones. For example, the parietal bone of the fox and calf has a curvature similar to that of humans, and fox and sheep cranial sutures may resemble some of the human skull sutures. Furthermore, these animals were selected because they are commonly found in the United Kingdom.

This presentation details the results of the analyses made on crania with GIS, demonstrating its potential in this aspect of forensic anthropology. Selected cranial sutures of all the skulls were mapped, and the curvature of specific cranial bones was measured. The measurements were then entered into a database. When cranial bone fragments are found, the sutures (if present) can be scanned and compared to the ones present in the database in order to ascertain if they are of human or non-human origin; the same process can be applied when measuring and comparing the bone curvature.

Though variations can occur, particularly related to age and/or pathological conditions, cranial sutures and curvature tend to follow a specific pattern in both human and non-human skulls. Therefore, they can be measured and compared with GIS, which was demonstrated to be a useful, fast, and non-destructive tool for the distinction between human and non-human cranial bone fragments in forensic anthropology.

Bone Fragments, GIS, Forensic Anthropology

A63 Application of Stable Isotope Forensics for Predicting Region-of-Origin of Unidentified Border Crossers Found Deceased in the United States

Eric J. Bartelink, PhD, California State University, Chico, Deparment of Anthropology, Butte 311, 400 W First Street, Chico, CA 95929-0400; Heather L. MacInnes, BS, 1775 E 8th Street, Chico, CA 95928; Julia R. Prince, BA, 1775 E 8th Street, Chico, CA 95928; Amy T. MacKinnon, BA, 400 W 1st Street, Chico, CA 95929; Lesley A. Chesson, MS, IsoForensics, Inc, 421 Wakara Way, Ste 100, Salt Lake City, UT 84108; Brett J. Tipple, PhD, IsoForensics, Inc, 421 Wakara Way, Ste 100, Salt Lake City, UT 84108; Krista E. Latham, PhD, University of Indianapolis, Biology Dept, 1400 E Hanna Avenue, Indianapolis, IN 46227; and Gregory E. Berg, PhD, DPAA Identification Laboratory, 310 Worchester Avenue, Joint Base Pearl Harbor-Hickam, HI 96853-5530*

After attending this presentation, attendees will understand the application of stable isotope analysis in predicting the region-of-origin of unidentified border crossers found deceased within the United States. Attendees will better understand the applications and limitations of stable isotope analysis as an investigative tool for forensic scientists in identifying foreign nationals.

The development of this form of forensic analysis will impact the forensic science community by demonstrating how stable isotope analysis can aid the repatriation process for unidentified border crossers from Latin America.

Over the past two decades, there has been a steady increase in the number of deaths of Unidentified Border Crossers (UBCs) along the United States-Mexico border. Since 1999, there have been more than 6,000 deaths in the United States border states (especially Arizona and Texas), representing Mexican, Central American, and South American nationals. The large volume of UBC casework has created an unprecedented human identification challenge, especially given the lack of personal documentation, antemortem records, and DNA family reference samples for these individuals.

Recently, a large-scale effort has been mounted to identify deceased UBCs recovered from Brooks County, TX. This area is along a major migration route from Mexico into Texas and has experienced a large number of UBC deaths in recent years. In 2013, Baylor University and the University of Indianapolis began the process of exhuming UBCs from this region to aid in personal identification efforts. Current efforts toward identification have focused on DNA, craniometrics, personal effects, and the use of missing persons databases.

Stable Isotope Analysis (SIA) can provide another investigative tool to aid in the identification effort of UBCs. Recently, SIA has been successfully used to provenance human remains from past wars and conflicts, as well as unidentified human remains cases from local jurisdictions. Stable isotope ratios measured in bones, teeth, and hair can provide a record of a person's dietary preferences, recent travel history, and childhood residence. Dietary information gleaned from stable carbon and nitrogen isotope values of bone collagen and bioapatite, tooth enamel bioapatite, and hair keratin provide useful information on an individual's food consumption practices during life. More importantly, stable oxygen and strontium isotopes in human tissues can be used to predict a region-of-origin. Because stable oxygen isotopes of water vary based on environmental factors, isotope ratios measured in bones and teeth reflect the local water source imbibed at the time of tissue formation. Strontium isotopes reflect geological age of a region's underlying bedrock and are incorporated into humans who consume plant and animal resources from the local landscape. When combined, these isotopes provide a powerful "geolocation" tool (i.e., an "isoscape") for predicting an individual's region-of-origin or travel history.

The goal of this study is to present stable isotope results and isoscape maps for a subset of UBCs (n=13) recovered from Brooks County, TX. Human bone and tooth samples were prepared for mass spectrometry, including stable carbon and nitrogen isotopes of bone collagen, stable carbon and oxygen isotopes of enamel bioapatite, and strontium isotopes of enamel.

Mean bone collagen $\delta^{13}C$ is -14.1‰ (±1.9, 1 Standard Deviation (SD); range=6.5) and mean $\delta^{15}N$ is 10.3‰ (±1.1, 1 SD; range=4.2). Tooth enamel bioapatite, which reflects childhood diet, is even more variable, with a mean $\delta^{13}C$ value of -6.8‰ (±2.4, 1 SD; range=7.6). As expected for individuals of Latin American origin, these mean values are consistent with a diet that emphasized C_4-based resources (e.g., corn products). The extent of dietary heterogeneity suggests that these individuals may be from different regions within Latin America; however, two individuals have especially low $\delta^{13}C$ bone and tooth bioapatite values and somewhat high $\delta^{15}N$ values, suggesting a diet more focused on C_3-based resources and higher trophic level protein sources.

For enamel bioapatite, mean $\delta^{18}O$ is -5.0‰ (±1.7, 1 SD; range=6.0). Isoscape predictions based on precipitation water maps are consistent with several Latin American countries for the majority of the sample. In at least one case, the $\delta^{18}O$ value is only consistent with an origin within the United States and in another case, only within the northeastern coast of South America. Stable isotope analysis can provide a useful investigative tool to aid in the identification effort of UBCs. The addition of the strontium isotope data should aid in narrowing down a more specific region.

Forensic Anthropology, Identification, Human

A64 What Level of Biogeographical Information Is Available From ^{18}O and ^{13}C Signatures in Late-Erupting Molars of Modern Humans?

Anastasia Holobinko, MS, Southern Illinois University, Dept of Anthropology, MC-4502, Carbondale, IL 62901; Wolfram Meier-Augenstein, PhD, Robert Gordon University, School of Pharmacy & Life Sciences, Sir Ian Wood Building, Garthdee Road, Aberdeen AB10 7GJ, UNITED KINGDOM; Helen F. Kemp, PhD, OEA Laboratories Ltd, Kelly Bray, Callington PL17 8EX, UNITED KINGDOM; Susan M. Ford, Southern Illinois University, Dept of Anthropology, MC4502, Carbondale, IL 62901; and Philip Turk, PhD, Colorado State University, Dept of Statistics, Rm 200, Statistics Bldg, Fort Collins, CO 80523*

After attending this presentation, attendees will better understand the forensic application of stable isotope analysis as it pertains to determinations of human provenance and the potential interpretive difficulties associated with analyses of enamel carbonate isotopic data.

This presentation will impact the forensic science community by illustrating the complexities associated with inferring geographic origins from isotopic data obtained from living individuals with self-reported dietary preference and residential history.

The goal of this presentation is to examine intra- and inter-tooth isotopic variability in the abundance of ^{18}O and ^{13}C in third molar enamel carbonate from individuals with self-reported dietary preferences and residential history and to explore this variability as an indicator of intra-individual variability.

Stable isotope analysis of biogenic tissues such as tooth enamel and bone mineral has become a well□recognized and increasingly important method for determining the provenance of human remains. Both ^{18}O and ^{2}H stable isotope signatures are well-established proxies as environmental indicators of climate (temperature) and source water and are therefore considered reliable indicators of geographic life trajectories of animals and humans.[1,2] Similarly, ^{13}C and ^{15}N abundance data have distinguished dietary preferences in ancient human populations, and have been used to qualify $_{2}H$ and ^{18}O geolocational data that may be consistent with more than one location.[3]

Third molar tooth enamel was sampled from ten living volunteers undergoing routine tooth extractions at Canadian dental clinics. Patients provided detailed residential history and answered questions pertaining to dietary preferences (e.g., vegetarian) prior to donating all four third molars. Enamel was drilled from the crown of two third molars from each subject, chemically cleaned, and subjected to an acid digest before being analyzed for their ^{18}O and ^{13}C composition using Isotope Ratio Mass Spectrometry (IRMS).

The pooled mean enamel carbonate $\delta^{13}C_{VPDB}$ value for all samples was suggestive of a persistent C_4 plant dietary influence at the time the sampled tooth enamel was forming. This is consistent with self-reported dietary intake information and residential history and with what is known about the typical North American diet.[4-6]

The pooled mean $\delta\ ^{18}O_{VSMOW}$ value for enamel carbonate from all samples was 24.39 ‰. Although subject variation was significant, neither diet nor sex significantly influenced the oxygen isotope data. Following conversion of $\delta\ ^{18}O_{Carbonate}$ values to $\delta\ ^{18}O_{Phosphate}$ values, drinking water $\delta\ ^{18}O$ values were calculated and compared to their corresponding regional estimated annual average $\delta\ ^{18}O$ values in precipitation retrieved from the Online Isotopes in Precipitation Calculator (OIPC).[7-9] No statistically significant correlations were evident between drinking water $\delta\ ^{18}O$ values and $\delta\ ^{18}O_{OIPC}$ values.

The overall lack of strong linear relationships between calculated drinking water $\delta\ ^{18}O$ values and precipitation $\delta\ ^{18}O$ values in this particular dataset illustrates the importance of considering site-specific isotopic complexities and using multi-isotope data obtained from multiple tissues when investigating the geographic origins of humans in an archaeological or forensic context. It is not possible to quantify intra-individual isotopic variability without sampling from larger populations and controlling for as many variables as possible. The construction of a database containing isotopic data obtained from a variety of environmental, human, and faunal tissue samples, and the application of such data to individual cases in which geographic origins are desired, is recommended.

While standardization of analytical methodology is critical to appropriate interpretations of the data, stable isotope profiling is not a stand-alone method and should be used in conjunction with other lines of evidence in determinations of human provenance.

Stable, Provenance, Identification

A65 Dental Non-Metric Analysis as an Aid to Undocumented Border Crossers (UBCs) Region-of-Origin Estimation

Rebecca L. George, MA, 9455 Sky Vista Parkway, Apt 10E, Reno, NV 89506; and Jorge Gómez-Valdés, PhD, Universidad Nacional Autónoma de México, Dept of Anatomy, Av. Universidad 3000, Mexico DF 04510, MEXICO*

After attending this presentation, attendees will better understand the application of dental non-metric analyses to the process of identifying deceased UBCs, as they help narrow an estimated region-of-origin for these individuals.

This presentation will impact the forensic science community by demonstrating the utility of dental non-metrics as a part of ancestry estimation within the biological profile, particularly in reference to how this methodology can contribute to the ongoing research seeking to increase UBC's identification rates.

Dental non-metric analyses have been used for more than 100 years in ancestry studies and were standardized through the establishment of the Arizona State University Dental Anthropology System (AUDAS) by Turner et al. in 1991.[1,2] Per Birkby et al., though, only two dental non-metric traits are utilized by the Pima County Office of the Medical Examiner (PCOME) in the UBC identification process.[3] This is not surprising, given that much of the recent UBC literature has focused on cranial and postcranial studies. Non-metric cranial studies primarily differentiate American Blacks and Whites from known UBC samples.[4-5] The metric postcranial study, though, found a need for population-specific formulas when working with known UBC individuals, as not all of the decedents originate from the same geographical location and, therefore, cannot be pooled under one ancestry umbrella term.[6] A craniometric study from within Mexico highlights this need for population-specific formulas as regional skeletal variation exists.[7] There is also a dental non-metric study that focuses on American Hispanic differentiation that highlights these same results from the aforementioned studies.[8] Edgar discussed the difficulty in distinguishing American Hispanic groups from one another when compared in a large study sample with American Whites and Blacks. The results of this study indicate that there may be potential for dental non-metric analyses when population-specific trait suites are established.

To explore the utility of dental non-metric analyses as they pertain to UBC individuals, samples were selected from Albuquerque, NM, Mexico City, Mexico, Zimapán, Hidalgo, Phoenix, AZ, and from unidentified UBC individuals housed at the PCOME, as well individuals from the Sacred Heart Burial Park from Falfurrias, TX, housed at Texas State University. Seventy-five American Southwest Hispanic (ASH) individuals were included in analysis, as well as 90 Mexican individuals and 33 unidentified UBC individuals; UBC individuals were either pooled or separated for certain analyses based on the small sample size of this group. These region-of-origin groups were selected based on the prevalence of UBC individuals that have been previously identified as Mexican at the PCOME and the need to determine any potential differences between ASH and foreign-born Hispanics. The dental non-metric data were collected according to the Arizona State University Dental Anthropology System (ASUDAS) standards and dichotomized for analyses.

A series of Pearson's chi-square and Fisher's exact tests to compare dental non-metric trait prevalence between each of the three region-of-origin groups demonstrated a lack of M_2 protostylid in the ASH sample (15.7%), while it was present in the Mexican (67.8%) and UBC (52.4%) groups in higher percentages of the total samples. The Lower Canine Distal Ridge (LCDR) (82.4%) and M_1 cusp 7 (53.8%) were more prevalent in the UBC group than in the ASH (49.1% and 25.0%, respectively) and the Mexican groups (42.1% and 25.0%, respectively). Furthermore, Mean Measure of Divergence (MMD) indicated that the ASH group differed significantly from the Mexican group (0.106) and the ASH group differed significantly from the UBC group from the Sacred Heart Burial Park (0.103).

These results indicate there are regional differences in dental non-metric trait prevalence among the ASH, Mexicans, and some of the unidentified UBCs included in these analyses. While there are limitations of this current research due to the samples selected for study, these are promising indications of the utility of dental non-metrics in UBC studies, nonetheless. Additionally, when placed in the framework of existing UBC literature, this research supports the assertions that population-specific trait suites and formulas are necessary to further the identification process of UBC individuals.

Dental Non-Metrics, Ancestry Estimation, UBC

A66 Comparative Study of Human and Non-Human Long Bones by Anatomical and Radiological Methods

Piyush Sharma, MD, All India Institute of Medical Sciences, Rm No-302, Dept of Forensic Medicine, New Delhi, Delhi 110029, INDIA; and Tabin Millo, MD, Department of Forensic Medicine, AIIMS, MMRDH, New Delhi 110029, INDIA*

After attending this presentation, attendees will better understand how human and non-human long bones differ when compared using some specific anatomic and radiological measurements, especially when only the mid-shaft of the bone is available, which is very difficult to identify.

This presentation will impact the forensic science community by providing new parameters and statically significant results from a comparative cross-sectional study in an area in which limited research is performed and will add to research being performed in forensic anthropology and forensic pathology by widening the prevalent view of the differences as well as use of new parameters for differentiating the mid-shaft region of long bones of human and non-human origin.

With skeletal remains, the first step is to determine whether or not the object in question is actually bone, and if so, then whether or not it is human. Many organic and inorganic materials can mimic bone (e.g., wood, stones, etc.)[1] When bones are incomplete or fragmentary, problems escalate rapidly. Cylindrical segments of the central shaft have little in the way of distinguishing features, apart from size. Burnt bone fragments offer similar problems due to heat distortion and shrinkage.[2] False samples of bones could be incorporated and claimed to be of human origin. Such cases lead to medicolegal complications such as whether the bones found could be linked to murder.

In this study, 30 human long bones of upper and lower limbs and 30 corresponding bones of *Capra aegagrus hircus* (goat) and *Ovis aries* (sheep) were used. This study was conducted at the Department of Forensic Medicine, at a tertiary care hospital in New Delhi after receiving ethical clearance. The continuous variables were compared in two groups by independent *t*-test and Wilcoxon rank sum test. Categorical variables were compared in two groups by using chi-square test and Fischer's exact test. The *p* value <0.05 was taken to be statistically significant.

The comparison of cortical thickness and ratio of cortical thickness to total diameter was statically significant when the group comparison was performed, which agrees with Croker et al.[3] But, when individual human bones were compared with non-human bones as a group, femur (p=0.39), fibula (p=0.45), humerus (p=0.57), and radius and ulna (p=0.34) showed no significant results for cortical thickness to total diameter ratio. When compared to the non-human counterpart, tibia (p=0.5) and fibula (p=0.22) showed no significant results. The mean ± Standard Deviation (SD) values for cortical thickness in this study for the human group was 5.36 ± 2.40 and for the non-human group was 2.89 ± 0.87 (p<0.05). In this study, the cortical thickness for the tibia in the mid-diaphyseal region had a median value of 8.87mm, similar to the findings obtained by Croker.[4] When compared with animal counterparts, cortical thickness to total diameter ratio was statically significant for the radius (p<0.05) and ulna (p<0.05) but was non-significant for the femur (p=0.39), tibia (p=0.5), humerus (p=0.57), and fibula (p=0.45). The median for human femur bones was 0.271 and for non-human bones was 0.198 (p=0.39). In this study, the length of the long bones and the presence of nutrient foramen in mid diaphyseal region doesn't differentiate between the two groups, which correlates with the studies by Chatrapathi and Shamsunder.5,6 For all long bones except the femur, a sharp border delineating the cortex and medulla in X-rays was present (p<0.05). For the fibula, humerus, radius, and ulna, parameters such as circumference at mid diaphyseal region, cortical thickness, antero-posterior diameter, presence of diaphyseal trabeculae, and cortical thickness to total diameter ratio were found to be insignificant.

In conclusion, this study attempts to shed light upon a gray and often neglected area — anthropology. This presentation will greatly impact criminologists and anthropologists, as it is a common scenario encountered in routine practice. This presentation will also help establish a baseline determinant for human bone differentiation, which will aid further studies and yield a fruitful medicolegal outcome. With the advent of modern scientific tests, human anthropometry has become a mere platitude of sorts; this study attempts to reach back to the grassroots of anthropometry and usher in a new scientifically backed method of human bone identification and differentiation.

Anthropometry, Skeletal Remains, Animal Bones

A67 Manipulation and Analysis of Virtual Bones: A Novel Method of Sex Estimation From the Mandible

Alice J. Butcher, BSc, Cranfield University, Cranfield Forensic Institute, Shrivenham, Oxfordshire SN6 8LA, UNITED KINGDOM; Roland Wessling, MSc, Cranfield Univeristy, Cranfield Forensic Institute, Shrivenham, Oxfordshire SN6 8LA, UNITED KINGDOM; Jessica Bolton, MSc, Cranfield University, Cranfield Forensic Institute, Defence Academy of the United Kingdom, Shrivenham SN6 8LA, UNITED KINGDOM; and Jelana Bekvalac, MSc, Museum of London, 150 London Wall, London EC2Y 5HN, UNITED KINGDOM*

After attending this presentation, attendees will better understand the use of 3D laser scanning to create virtual models of human skeletal remains and how these models can be automatically manipulated and analyzed in novel ways to build up a biological profile. The principles involved in these processes are exemplified through a feasibility study on automated sex estimation using topographical analysis of the mandible.

This presentation will impact the forensic science community by highlighting the capabilities and advantages of automated, computer-based anthropological analysis and by introducing a new avenue for sex estimation of skeletonized human remains.

Analysis of virtual osteological material is an emerging field in physical anthropology, conferring advantages over traditional methods in areas such as reproducibility, data handling, and retention, as well as range of possible measurements and unique analyses available. This study, which is part of the Virtual Skeletal Analysis (ViSA) Project, attempted to apply these principles to the mandible with regard to sex estimation.

Thirty-four complete, non-pathological human mandibles from the St. Bride's Church crypt collection in London were digitized using hand-held laser topography. Using a tailor-made R[1] package based on the geometric properties of the bones, each resulting point cloud was manipulated into a standardized orientation. The exterior surfaces of the posterior ramus borders and mandibular angles were separated from the main body and re-oriented for further analysis.

A triangular mesh network was formed over the point clouds representing the posterior rami and mandibular angles and these were analyzed for mean slope, mean aspect, and size (2D area, 3D surface area, and valley volume) using Geographic Information Systems (GIS) software; an uncommon approach in anthropological analysis that has never previously applied to the mandible. This software treats the bone surface as a miniaturized landscape, providing a unique and quantifiable method of analyzing bone morphology.

It was found that both the posterior rami and mandibular angles were sexually dimorphic in terms of size, either bilaterally or unilaterally (particularly on the right side), and in the mean slope of the left posterior ramus. Preliminary demarcation points for the estimation of sex were created and tested for each sexually dimorphic analysis. The 2D area of the right posterior ramus and valley volume of the right mandibular angle were each independently able to correctly sex over 80% of the sample.

This particular methodology must be tested on further samples to confirm and refine its findings; however, the study successfully revealed a largely unexplored territory of anthropological analysis, with great capacity to expand. The study especially exposed the dearth of specialized software for the virtual analysis of skeletal material, despite the considerable advantages and potential for the field.

Virtual, Skeletal, Analysis

A68 Calcium and Phosphorus Detection Using Benchtop vs. Hand-Held X-Ray Fluorescence (XRF) Spectrometers

Aaron R. Kuzel, BS, Lincoln Memorial University - DeBusk, College of Osteopathic Medicine, 6965 Cumberland Gap Parkway, Harrogate, TN 37752; Angi M. Christensen, PhD, FBI Laboratory, 2501 Investigation Parkway, Quantico, VA 22135; and Susan M. Marvin, PhD, FBI Laboratory, 2501 Investigation Parkway, Quantico, VA 22135*

After attending this presentation, attendees will be familiar with the different detection levels of calcium and phosphorus when using hand-held and benchtop XRF spectrometers.

This presentation will impact the forensic science community by confirming that XRF-generated Calcium to Phosphorus (Ca/P) ratios using either hand-held or benchtop XRF devices are a valid criteria for distinguishing between different material sources and by highlighting the need for users to evaluate Ca/P ratios in reference to those made under similar analytical conditions.

The analysis of skeletal remains (or potential skeletal remains) for chemical and elemental properties is becoming increasingly common in forensic anthropological investigations. XRF is one method of elemental analysis that has been used with increasing frequency, in part due to its ease of use and the fact that little to no sample preparation or destruction are required. XRF analyses have traditionally been performed in a laboratory setting using large benchtop XRF spectrometers. These machines offer a variety of benefits including the ability to control and vary the testing atmosphere. Recently, portable or hand-held XRF units have been developed, with the advantage of being able take the device into the field to perform preliminary or conclusive field tests *in situ* or even for use in a laboratory setting while minimizing the instrument footprint; however, these portable devices may pose potential analytical complications in forensic anthropological cases due to the fact that analyses are all performed in open air, which may affect phosphorus detection since elements of low atomic number are at risk of significant absorption by air. This presentation examines the detection of calcium and phosphorus using two different XRF instruments, a benchtop and a hand-held, and compares results.

Calcium and phosphorus content in osseous and dental material from human and non-human sources were measured by XRF to obtain Ca/P ratios. Samples were cut using a diamond wafering saw to reveal cross sections with flat, smooth surfaces for measurement and included human and non-human (cow, deer, and pig) bones as well as teeth from human, deer, and pig. Shell and coral samples (which are known to have high levels of Ca but little to no P) were also examined. A control sample consisting of calcium hydroxyapatite powder was also analyzed.

Samples were analyzed under three conditions using two XRF instruments. Specimens were analyzed in both air and vacuum atmospheres using a benchtop spectrometer and were analyzed in air using a field-portable XRF. The X-ray tubes of both instruments were operated in unfiltered conditions with an excitation voltage of 20kV. The collection time was maintained consistently at 100 seconds live time. Spectral analysis was performed using instrumental software, and calcium and phosphorus emissions were used to calculate Ca/P ratios using the counts detected in the region of each of the peaks summed over five channels.

Analysis of Variance (ANOVA) shows highly significant differences in Ca/P ratios obtained under the three analysis conditions for individual sample groups as well as for all bones combined. These differences are due in part to overall differences in the detection of both elements, but differences in the detection of phosphorus contribute most significantly. Detection levels for both elements were overall lowest using the hand-held instrument. Detection levels for both elements were greater when using the benchtop in air and greatest when analyses were performed on the benchtop in a vacuum.

Calcium and phosphorus are both measureable under all three analytic conditions included in this study; however, since the calcium and phosphorus signals are attenuated differently by air, comparing measurements made under different atmospheric conditions may be misleading. To use XRF-generated Ca/P ratios to evaluate skeletal versus non-skeletal origin, measurements should be made under consistent analytical conditions. That is, known skeletal and non-skeletal samples should be evaluated to establish the performance of an instrument and specific measurement conditions prior to attempting to evaluate an unknown. When measured under the same conditions, XRF-generated Ca/P ratios are valid criteria for distinguishing differences between material sources.

Forensic Anthropology, Elemental Analysis, XRF

A69 Osteometric Reassociation Through Quantifying Long Bone Size and Shape and Prediction Using Bayesian Regression Via Hamiltonian Markov Chain Monte Carlo (MCMC)

Kyle A. McCormick, MA, 805 Deery Street, Knoxville, TN 37917*

After attending this presentation, attendees will be informed about methods for quantifying long bone morphology and using these data in a predictive framework for resolving small-scale, closed-population commingled assemblages.

This presentation will impact the forensic science community by integrating information on long bone shape into osteometric sorting models that largely rely on size as assessed through standard osteological measurements. Additionally, this presentation introduces a novel predictive framework for osteometric reassociation: Bayesian regression via Hamiltonian MCMC.

Commingled assemblages present a common situation in osteological analysis where discrete sets of remains are not readily apparent, thereby hindering biological profile construction and the identification process. Of the methods available for resolving commingling situations, osteometric sorting is reliable and relatively objective.[1] Current osteometric sorting methodology models long bone relationships by calculating a distance measure from standard osteological measurements, transforming that distance measure into a test statistic, and evaluating the value of that statistic against the appropriate distribution to arrive at a *p*-value.[1] This methodology is a decision-making, error-mitigation approach, where possible matches are eliminated if the accompanying *p*-value exceeds an analyst-defined threshold.[1] Elements are reassociated if all other possibilities are eliminated and the assumption of a closed-population is met (see reference 1 for a more nuanced consideration of this approach and its statistical foundation).

The primary goals of the current study are three-fold: (1) examine the reliability (as assessed through correct classification rates) of a predictive framework for reassociation; (2) study the utility of predictive probabilities and typicality values as metrics for reassociation; and, (3) incorporate information on long bone shape from geometric morphometric landmark data into osteometric reassociation models.

To accomplish these goals, landmark data were collected from the long bones of 208 subjects, males (n=103) and females (n=105), between 19 years and 62 years of age at death, from the William M. Bass Donated Skeletal Collection. Raw landmark data were fit using generalized Procrustes analysis to extract log-centroid size and Procrustes coordinates. Procrustes coordinates were subjected to Partial Least Squares (PLS) analysis to extract relevant components. After the sample was transformed into log-centroid size (size variable) and PLS components (shape variables), ten individuals were randomly removed from the total sample, acting as a small-scale, closed-population commingled assemblage. One element was chosen from the commingled assemblage as the independent variable, with the ten possible matching elements representing the dependent variable. Using the remaining total sample, Bayesian regression via Hamiltonian MCMC was used to estimate a range of possible dependent variable values. These values were smoothed into a probability density function using kernel density estimation and the ten possible matches were evaluated against this distribution to calculate predictive probabilities and typicality values. The element with the highest predictive probability was considered the best match. Femur antimere comparisons illustrate the utility of this approach.

Over the course of 1,000 simulations, matches were correctly classified for 77.6% of the commingled assemblages. When size and shape were analyzed separately, correct classification dropped to 51.1% and 60%, respectively. Despite the high classification rate, predictive probabilities for correctly classified matches were equivocal, with a mean value of 0.1755 and a range of 0.1164-0.2973. These values were similar to predictive probabilities of incorrect classification (mean: 0.1502, range: 0.1159-0.2649), suggesting predictive probabilities alone were a poor means of identifying classification error. Typicality values were minimally helpful in identifying classification error, with mean typicality values for correct and incorrect classifications of 0.8541 and 0.6919, respectively. Additionally, typicality values for both correct and incorrect classifications ranged all possible values.

These results suggest that bones can be reliably reassociated using the predictive framework detailed above. The osteometric reassociation model presented incorporates both shape and size information, providing a more complete representation of long bone form over standard osteological measurements. Additionally, Bayesian parameter modeling results in a distribution of possible values for the independent variable, directly modeling uncertainty in its estimation; however, practical applications of this model are currently limited by a means to detect classification error, as predictive probabilities and typicality values are similar for both correctly and incorrectly classified matches.

A70 A Simple Method for Estimating Subject-to-Camera Distance for Legitimate Craniofacial Superimpositions

Carl N. Stephan, PhD, The University of Queensland, School of Biomedical Sciences, Saint Lucia, Queensland 4072, AUSTRALIA*

After attending this presentation, attendees will be introduced to a simple method for estimating face-to-camera distance from frontal facial photographs using face anatomy alone (palpebral fissure length) when focal length of the lens is known. This presentation will also compare accuracy of these results to those acquired using camera-to-subject distances extracted from the metadata of the corresponding digital image files (another technique that so far has gone uncommented upon in the superimposition literature). Normally, the inclusion of an inanimate object, or smiling expression with a view of teeth, in a facial photograph is thought to be required for matching skull-to-camera distance to face-to-camera distance in craniofacial superimposition. This is not true.

This presentation will impact the forensic science community by providing new simple methods for matching skull-to-camera to face-to-camera distances, as required for perspective distortion matching, when undertaking one-to-one anatomical comparisons in craniofacial superimposition.

Like any forensic science technique, video superimposition should be a scientifically robust procedure, subject to strict performance criteria. One of these criteria must be that the perspective distortions between the two images that are superimposed are the same, so that one-to-one anatomical comparisons can be undertaken. This requires knowledge about what subject-to-camera distance was used to acquire the facial photograph under analysis, but presently this is said to be impossible unless the photographer who took the photograph can be contacted (e.g., Sekharan says, "it is almost an impossible task to determine (subject-to-camera) distance exactly from the photograph").[1]

This study took frontal photographs of four subjects in the "lip shut" posture (one adult male, one adult female, one sub-adult female, and one juvenile male) with a known objective lens length (100mm) at distances between 1m and 10m serially increasing by 1m and used a relatively invariant facial trait (palpebral fissure length) to calculate face-to-camera distance with the formula: $d=f(1+a/b)$, where d=face-to-camera distance (m), f=focal length (mm), a=real-life object size (mm), and b=object size on the image receptor.

Using this method across all ten measurement scenarios for each subject, results indicate a mean percentage error of 7% (range=3.5%-10%) for face-to-camera distance estimation, which falls well within the tolerance levels to obtain <1% difference in facial dimensions at life size due to perspective distortion differences between photography sessions. Palpebral fissure measurement is, thereby, verified as a suitable method for gauging face-to-camera distances. Compared to subject-to-camera distance information extraction from the photographic file's metadata, the palpebralfissure measurement performed superiorly with only 8% absolute error compared to 23% error for the metadata.[2] This unambiguously verifies the palpebral fissure measurement as useful for craniofacial superimposition and as a cross-check of recalled photographic parameters by photographers reporting to have taken the original facial photograph.

Forensic Anthropology, Video Superimposition, Perspective Distortion

A71 Texture Mapped Average Skulls Created From Standardized Photographs Using the Perception Lab's Psychomorph

Jodi M. Caple, BS, The University of Queensland, School of Biomedical Sciences, Saint Lucia, Queensland 4072, AUSTRALIA; and Carl N. Stephan, PhD, The University of Queensland, School of Biomedical Sciences, Saint Lucia, Queensland 4072, AUSTRALIA*

After attending this presentation, attendees will be aware of highly realistic, sex-specific, mathematically average photographs of skulls for South African Black and White, American Black and White, and Japanese population groups.

This presentation will impact the forensic science community by providing, for the first time, photographic-quality average skulls to objectively illustrate skull morphotypes.

To date, "typical" skulls for each group have been represented either by average linear measurements or Cartesian coordinates, descriptions of morphoscopic trait frequency, or diagrams (drawings or photographs) of single skulls thought to represent the morphotype well. While these methods are important for determining sex and ancestry to aid in identification, they do not allow accurate visualization of what the average skull for each group would look like. Current depictions of each group rely either on diagrams that caricaturize typically observed morphoscopic traits or on a single individual as representative of an entire population. The central tendency, being the most widely used measure for normally distributed data, is a natural choice to more accurately visualize depictions of skulls classified according to particular groups. This was undertaken for this study by: (1) taking standardized photographs of skulls in anterior and left lateral views; (2) outlining the skull shape; (3) calculating the average shape; (4) warping individual photographs to the average shape; and, (5) averaging the color information of the warped photographs to obtain the final average shape and color result.[1] This method has previously been successfully applied to face photographs, producing average faces for individuals (males and females) of self-reported European and Central/Southeast Asian origins.[2]

Standardized photographs were taken of skulls in an anterior view and left lateral view, sourced from the Pretoria Bone Collection, the Hamann-Todd Collection, and the Chiba Bone Collection. Photographs were taken using a full-frame Digital Single-Lens Reflex (DSLR) camera fitted with a 100mm lens, and a camera-to-object distance of 1.2m. Each image was manually delineated by positioning landmarks that were then joined with contour lines to form the outline delineation map. This map was created for each and every skull photograph in this study, and the map was specific to the photographic view. The average x and y coordinate position of each landmark was then used to form the average delineation map, which was used to warp each individual image to the average shape. The average color information for each pixel was then applied for each group to produce the final images.

These average images provide the first quantified basis for depicting skulls grouped by sex and ancestry. They can serve as exemplar images for sex and ancestry, eliminating the need for caricaturized diagrams or isolated single examples drawn out of the sample distribution.

A72 New Forensic Archaeological Recovery Protocols for Fatal Vehicle Fires

Alexandra R. Klales, PhD, Mercyhurst University, Dept of Applied Forensic Sciences, 501 E 38th Street, Erie, PA 16546; Dennis C. Dirkmaat, PhD, Mercyhurst University, Dept of Applied Forensic Sciences, 501 E 38th Street, Erie, PA 16546; and Luis L. Cabo, MS, Mercyhurst University, Dept of Applied Forensic Sciences, 501 E 38th Street, Erie, PA 16546*

After attending this presentation, attendees will be familiar with new forensic archaeological protocols applicable to fatal vehicle fire scenes that result in the efficient and effective recovery of human remains and associated evidence.

This presentation will impact the forensic science community by highlighting the benefits of employing modified forensic archaeological techniques in the documentation and recovery of the fatal vehicle fire scene. Furthermore, the forensic science community can employ the detailed recovery protocols being presented for fatal vehicle fire recoveries.

Fatal fires are one of the most complex scenes to recover, primarily because materials at the scene are heavily modified. In particular, human remains appear homogenous in color with the surrounding burned matrix and they become very fragile due to the taphonomic modifications of fire and subsequent suppression efforts by first responders. Too often, remains are quickly pulled from the fire debris with no documentation of body positioning or of the relationship of the remains to other physical evidence. The complexity of fatal fire scenes and the current recovery protocols for these types of recoveries often result in the human remains and evidence being missed, damaged, or destroyed in their entirety.[1] This in turns hinders autopsy, positive identification, and laboratory and bone trauma analysis of the remains.

Of approximately one million fires per year in the United States, 13.3% are vehicle fires.[2] Fatal vehicle fires are hybrid scenes with combined characteristics of both indoor and outdoor scenes. Much like indoor scenes, the general structure of the burned vehicle is preserved, thereby providing permanent reference points and simplifying mapping; however, the quantity of material, impact of taphonomic agents, and the potential stratigraphic relationships of remains and evidence are all features consistent with outdoor crime scenes. There are other complexities unique to vehicle fires that warrant specific recovery protocols that differ from indoor scenes, outdoor scenes, or fatal structure fires. First, vehicle fires almost always have accelerants present (i.e., gasoline) that impact how the vehicle burns. Second, components of the vehicle, such as the magnesium steering column, create an exploding effect that mirrors the dispersal of materials more commonly encountered with bomb blasts or mass disaster scenes. Last, vehicle fires are more contained and are somewhat easier to process than structure fires due to their smaller size. Often, it is easier to identify the location of the human remains very quickly in vehicle fires.

The new protocols being presented for fatal vehicle fire recoveries are based on and modified from the protocols developed by Dirkmaat et al. for burned structures and are based on field exercises and past case studies.[3] A summary of the newly developed protocols is as follows: (1) overall scene documentation (photographic, written, and spatial team with barcoding system) that continues throughout recovery; (2) pedestrian line search to flag evidence and remains; (3) determination of significance; (4) preparation of the vehicle for recovery (i.e., removal of the roof, trunk, and doors); (5) establishment of a mapping system (i.e., subdivide vehicle into regions using a baseline or grid system); (6) excavation of individual units using trowels, dustpans, and labeled buckets; (7) hand sorting of debris on tarps and screening through ¼" mesh; (8) full exposure of the remains *in situ*; (9) creation of a plan-view map detailing positioning of the remains and associated evidence; (10) mapping of the grid system by the provenience team to later be geo-referenced to the hand-drawn map; (11) wrapping of loose elements and fragile bones with heavy-duty plastic wrap; (12) removal of the remains using body bags and backboards to stabilize the body during transport; (13) collection of loose pieces in labeled containers or bags for re-association in the laboratory; and, (14) excavation beneath the remains following removal.

The implementation of these new protocols using modified forensic archaeological methods results in a nearly 100% recovery of remains and physical evidence in a timely manner, while also limiting disturbance and damage of the remains during the recovery of fatal vehicle fires. Furthermore, detailed mapping and photographs provide precise information on contextual relationships of the remains and evidence at the scene following recovery.

This project was funded in part by the National Institute of Justice, United States Department of Justice.

A73 Forensic Examination of Burned Human Skeletal Remains: Shifting the Paradigm

David Gonçalves, PhD, Research Centre for Anthropology and Health, University of Coimbra, Coimbra, PORTUGAL; João Pedro Valente de Oliveira Coelho, MSc, University of Coimbra, Dept of Life Sciences, Calçada Martim de Freitas, Coimbra 3000-456, PORTUGAL; Calil Makhoul, MSc, University of Coimbra, Dept of Life Sciences, Calçada Martim de Freitas, Coimbra 3000-456, PORTUGAL; Inês Santos, MSc, University of Coimbra, Dept of Life Sciences, Calçada Martim de Freitas, Coimbra 3000-456, PORTUGAL; Ana Vassalo, MSc, University of Coimbra, Dept of Life Sciences, Calçada Martim de Freitas, Coimbra 3000-456, PORTUGAL; Maria Teresa Ferreira, PhD, Forensic Sciences Centre, University of Coimbra, Coimbra, PORTUGAL; Luis A.E. Batista de Carvalho, PhD, University of Coimbra, Dept of Chemistry, Molecular Physical-Chemistry R&D Unit, Coimbra 3004-535, PORTUGAL; and Eugenia Cunha, PhD, Universidade de Coimbra, Dept of Life Sciences, Laboratory of Forensic Anth, Calçada Martim de Freitas, Coimbra 3000-456, PORTUGAL*

After attending this presentation, attendees will better understand Heat-Induced Changes (HIC). Additionally, current methods for assessing the biological profile, when applied to burned skeletal remains, will be improved.

This presentation will impact the forensic science community by proposing new approaches to the analysis of burned skeletal remains and by providing knowledge obtained from the research carried out in the framework of the ResearcH PrOject of the 21st-Century Skeletal Collection (CEI/XXI) Burned SkeleTons (HOT).

The forensic analysis of burned skeletal remains is often complicated by HIC because they interfere with the application of standard methods. Probably the most obvious difficulties are related to fragmentation and to the inability in assessing the extent of HIC — namely concerning dimensions and warping — affecting a particular bone or tooth. Despite the increase in the amount of research, a reliable method to estimate this extent is still escaping us. At the University of Coimbra in Portugal, skeletons from the CEI/XXI are being experimentally burned under controlled conditions.[1] The main objectives of this project are: (1) to achieve a better understanding of HIC; (2) to test the reliability of current methods for assessing the biological profile, when applied to burned skeletal remains; and, (3) to develop new analytical methods more specific to burned skeletal remains according to the extent of burning.

Unclaimed skeletons from a public cemetery donated to the University of Coimbra are being compiled, allowing for invasive procedures such as burning. Only the right antimeres of each skeleton are subject to controlled burning (up to 1,050°C) while unpaired bones such as the cranium are not being burned. The unburned bones serve as a basis for comparison. Analyses of the skeletons are performed before and after burning to document color, weight, and morphological and dimensional changes. Comprehensive research on burned skeletal remains is already underway, although the current sample size is still small (n=20).

The potential of cementochronology for age estimation on calcined teeth has been investigated. Although the estimated age through Tooth Cementum Annulations (TCA) presented poor agreement with chronological age (mean error=24.2 years), partly due to the poor visibility of the lines, a new cementochronological approach based on the estimation of the amount of TCAs present in each tooth provided better results (mean error=11.4 years). In addition, an attempt to determine the effect of bone collagen on the occurrence of heat-induced warping was conducted. Although a slight significant effect (p=.040) was indeed found, multivariate statistics identified other more significant factors in the model: maximum temperature (p<.001); duration of combustion (p<.001); sex (p<.001); and age at death (p=.010). The results demonstrated that warping can occur on bones with both low and highly preserved collagen contents, suggesting that the role of the burning dynamics is particularly important. As a result, warping appears to be an unreliable indicator of the pre-burning condition of skeletal remains (fleshed vs dry). In another research project, the focus is on the potential of geometrics morphometrics to assess the pre-burning shape and size of burned bones. A multivariate approach is being adopted to determine if these parameters — usually impossible to assess during the examination of burned remains — can be reliably obtained through virtual retro-deformation. Initial results show some promise, although additional research is needed.

Several incidents involving fire (e.g., airplane crashes, terrorist attacks, bush fires) can result in victims whose remains are skeletonized and burned. Experimentation with human remains is critical since other species may not serve as reliable proxies. A good documentation of HIC and the validation of analytical methods are also fundamental. Controlled laboratory burnings do not always replicate the usual on-and-off burning exposure occurring in some forensic scenes; also, dry bones may react differently than fleshed or green bones.[2] These are some of the shortcomings of this new collection, but it still allows important insights about HIC, and its contribution for the improvement of more adequate bioanthropological methods for the analysis of burned bones and teeth is undisputable.

Burned, Skeleton, Forensic

A74 Remote Sensing of Human Burials

Katie Corcoran, BS, 250 S Stadium Hall, Knoxville, TN 37996; Amy Z. Mundorff, PhD, University of Tennessee, Dept of Anthropology, 250 S Stadium Hall, Knoxville, TN 37996; Devin White, PhD, Oak Ridge National Laboratory, 1 Bethel Valley Road, Oak Ridge, TN 37830; and Whitney Emch, PhD, National Geospatial-Intelligence Agency, 7500 Geoint Drive, Springfield, VA 22150*

After attending this presentation, attendees will understand some principles of remote sensing, some characteristics of human burial disturbance that are observable in remotely sensed data, and an example of some analytical approaches to separating disturbance signatures from non-disturbance signatures using an unmarked burial dataset collected at the University of Tennessee Anthropology Research Facility (ARF).

This presentation will impact the forensic science community by providing documented evidence of topographic and spectral signatures for use in narrowing areas-of-interest thought to contain buried human remains, as well as other types of ground disturbances. Further, this research is unique in that it separates signatures of truly clandestine disturbance targets by comparing like-materials (e.g., affected live vegetation to unaffected live vegetation).

In addition to an empty control grave, ten donated human bodies were buried in three differently sized graves at the ARF in February 2013, for a total of four disturbance targets. In 2013 and 2014, multiple terrestrial Light Detection and Ranging (LiDAR) and spectral datasets were collected using a tripod-mounted laser scanner and a portable spectroradiometer (350nm-2,500nm), respectively. These datasets were subjected to rigorous statistically based data reduction methods to maximize their separability. LiDAR point clouds were filtered using pre-defined local elevation thresholds to remove non-ground points, and reflectance spectra were filtered to remove wavelength bands not significantly contributing to a binary presence/absence disturbance classification in training data.

Filtered LiDAR data reveal distinctive burial footprints, expressed as subtle depressions that are especially apparent in elevation change images and range from -10cm–0cm. Elevation loss is most pronounced directly over buried human bodies due to the redistribution of mass from decomposition, in addition to normal soil settling. Unsurprisingly, these depressions fill in with debris over time, resulting in diminished visibility; however, the two largest burials were still clearly visible in LiDAR data collected at 22 months post-burial.

Statistical analysis of spectra reveals separation in the visible and infrared regions of the spectrum. A Discriminant Function Analysis (DFA) results in the correct classification of 60.0% of disturbed vegetation (n=70) and 54.8% of non-disturbed vegetation (n=84) in the spring season and 74.1% of disturbed vegetation (n=54) and 60.8% of non-disturbed vegetation (n=79) in the autumn season using cross-validation. Binary Logistic Regression (BLR) results in the correct classification of 54.3% of disturbed vegetation (n=35) and 76.2% of non-disturbed vegetation (n=42) in the spring season and 55.6% of disturbed vegetation (n=27) and 74.3% of non-disturbed vegetation (n=39) in the autumn season using a separate validation sample. It is likely that a hybrid statistical model will successfully exploit the high rate of correct DFA disturbance classification and the high rate of correct BLR non-disturbance classification to achieve optimal results. Experimentation with machine-learning approaches suggests they may be useful for reinforcing statistically based predictive models under certain seasonal and technological conditions.

This presentation will demonstrate the importance of using multiple datasets for isolating small or subtle targets when it makes sense to do so, as it does in clandestine human burial scenarios. This presentation will highlight important considerations for these findings, including how ground-based data can be used on its own or in combination with other intelligence and data to inform remote aerial and orbital data collections. Additionally, this presentation will cover some practical ways investigators might use these findings on the ground to facilitate rapid decision making.

Forensic Archaeology, Remote Sensing, Victim Recovery

A75 The Use of Near-Infrared Remote Sensing in the Detection of Clandestine Human Remains

Marilyn Isaacks, BA, Texas State University, 15931 Watering Point Drive, San Antonio, TX 78247; and Daniel J. Wescott, PhD, Texas State University, Dept of Anthropology, 601 University Drive, San Marcos, TX 78666-4684*

After attending this presentation, attendees will better understand the potential uses of unmanned aerial drones in the detection of clandestine human remains during search missions.

This presentation will impact the forensic science community by introducing a new use for existing drone technology that will allow forensic investigators to quickly, inexpensively, and safely search for clandestine human remains.

Most commonly, searches for clandestine remains have utilized time-consuming methods such as line searches that require the support of many individuals to scour a typically large area. While these methods do yield results, they take time to execute and, in certain places, may actually prove dangerous for the participants.[1] Many additional methods have been tested and utilized in the recovery of human remains, including the use of metal detectors, aerial photography, and ground-penetrating radar, which can be time consuming and expensive.[2] Only in recent years has the use of Near-Infrared (NIR) imagery been experimented with as a means of uncovering clandestine graves and surface remains.[1-3]

As human remains decompose, a large amount of organic matter enters into the surrounding soil, forming a Cadaver Decomposition Island (CDI).[4] Because soils that are organically rich have a different reflectance signature than nearby unaffected soils when viewed with NIR imaging, it is likely that by using NIR photography and drone technology, clandestine remains may be recovered more quickly and more efficiently than has previously been possible.[3] Because NIR photographs can be obtained using small, remotely controlled aircraft or aerial drones, large areas can be surveyed for clandestine remains remotely and rapidly, thereby minimizing the need to involve a substantial group of people in the search. In so doing, potentially dangerous locations can be searched without great risk, disturbances to forensically significant sites will be minimized, and the area that personnel must search will be reduced and more precisely understood.

The present study explores the utility and longevity of NIR cameras mounted to Unmanned Aerial Systems (UAS) in the detection of clandestine human remains. Aerial NIR photographs and soil samples were compiled from 104 identifiable CDIs (i.e., the fertile soil area below and surrounding a decomposing cadaver) at the Forensic Anthropology Research Facility (FARF) at Texas State University in San Marcos, TX. Four surface soil samples were taken from each CDI on the day of the first drone flyover, two from the center, and two from the edge. Half of the soil samples collected from the center of each CDI were sent for analysis of organic materials (specifically organic carbon and nitrogen) at Texas A&M, Department of Soil and Crop Science, while the other half were burned in a muffle furnace at Texas State University to estimate the amount of total carbon within each sample based on the difference between initial soil weight and the ash weight. Each area of FARF that contains or once contained human remains was photographed using a camera with NIR capabilities mounted on UAS. Unused areas of FARF were also examined to determine whether natural disturbances create signatures similar to that of human decomposition.

Results of an unpaired *t*-test show a significant difference ($p<0.001$) between the NIR spectra signature of true placements (i.e., CDIs) versus that of control sites. Baseline trends indicate that CDIs that are more than approximately two years old cease to be visible in the NIR spectra, while CDIs that are younger than two years, but older than one week, are easily distinguishable from the surrounding soil. While no single chemical factor in the present study has a significant effect on the strength of the NIR signature of a given CDI, a multiple linear regression of organic carbon, total nitrogen, and total carbon presents a strong correlation coefficient ($R=0.670$) between the variate and the strength of the NIR spectra signature. Analysis of Variance (ANOVA) results further indicate that this model does significantly predict the strength of the signature (F (3, 58)=14.647, $p<0.001$).

In conclusion, this study demonstrates the utility and efficiency of unmanned aerial drones mounted with NIR-capable cameras in the remote detection of clandestine human remains. The combination of organic materials such as nitrogen and carbon purged from the body during decomposition creates a unique signature that is visible in the NIR spectrum up to two years after its creation and can be used as a tool on search missions for clandestine human remains.

Clandestine Remains, Aerial Drones, Remote Sensing

A76 The Interpretation of Human Pediatric Cranial Fracture Patterns Using Experimentally Generated Porcine Ground-Truth Data

Jennifer M. Vollner, MS, 354 Baker Hall, East Lansing, MI 48824; Caitlin C.M. Vogelsberg, MS, Michigan State University, Dept of Anthropology, 354 Baker Hall, East Lansing, MI 48824; Patrick E. Vaughan, BS, Michigan State University, Orthopaedic Biomechanics Laboratories, E Fee Hall, Rm 407, East Lansing, MI 48824; Todd W. Fenton, PhD, Michigan State University, Dept of Anthropology, 354 Baker Hall, East Lansing, MI 48824; Steven C. Clark, PhD, Occupational Research and Assessment, 124 Elm Street, Big Rapids, MI 49307; and Roger C. Haut, PhD, Michigan State University, Orthopaedic Biomechanics, A407 E Fee Hall, East Lansing, MI 48824*

After attending this presentation, attendees will be aware of: (1) the existence of the Pediatric Cranial Fracture Pattern Registry (PCFPR); (2) the applicability of experimental porcine cranial fracture-pattern data to human pediatric forensic cases; and, (3) the medicolegal implications of these data for cranial fracture-pattern interpretation.

The presentation will impact the forensic science community by demonstrating the value of ground-truth porcine experimental data in the interpretation of pediatric deaths involving blunt force cranial trauma when the injury history is unknown or of questionable reliability.

Pediatric deaths involving cranial fractures are challenging cases and increasingly call for a multi-disciplinary investigation to interpret injury mechanism and aid forensic pathologists in the determination of the manner of death. In response to these challenges, the PCFPR was recently established at Michigan State University and contains 206 de-identified pediatric death cases involving blunt force cranial trauma submitted by 15 partnering medical examiner offices. This resource was established to provide investigators with an assessment tool that links fracture patterns with provided injury scenarios.

Because limited human experimental ground-truth data exists linking cranial fractures with known scenarios, this study's laboratories have developed a porcine model and performed a series of studies to investigate the effects of surface shape and energy level on cranial fracture initiation and patterns.[1,2] With this foundational work in place, it is now necessary to begin relating the experimental findings to human forensic cases. This study applied the findings from previous research to interpret cases in the PCFPR. It was hypothesized that it would be possible to distinguish cranial fracture patterns produced by focal blunt impacts from fracture patterns generated by impacts onto a flat surface based on this previous research.

A total of 86 homicide cases with fracture pattern diagrams and forensic pathology observations were examined to determine whether the injuries were consistent with flat or shaped impact surfaces. Methods employed in this study were developed from the results of the aforementioned research projects in which infant porcine specimens were subjected to impacts at the center of the right parietal from various shaped implements including: flat surfaces, a 90^{o} edged surface, a 2-inch diameter sphere, a five-eighths-inch diameter sphere, and a one-quarter-inch diameter flat-ended cylinder. These studies demonstrated that fracture patterns are dependent on impact surface shape. Specifically, flat surfaces result in peripherally initiated fractures whereas more focal contact surface shapes resulted in more fractures initiating at the point of impact, curvilinear fractures, and/or areas of depression. These same fracture patterns were investigated in the PCFPR homicides.

The results of this study include the classification of these 86 cases into the following categories: impacts to flat surfaces, non-flat/shaped surfaces, and those that could not be presently classified. Twenty-seven cases (31%) had peripheral fractures, which were most consistent with flat surface impacts, while 24 cases (28%) expressed injuries characteristic of shaped impact surfaces, either in isolation or in conjunction with one another. This is a conservative estimate as several cases exhibited confounding cranial fractures, making them difficult to classify. This left 35 cases (41%) unclassified. Of the cases classified as non-flat, 13 (15%) had fracture patterns consistent with point-of-impact fracture initiation, 8 (9%) presented curvilinear fracture patterns, and 14 (16%) expressed areas of depression. It is noteworthy that several of the non-flat impact cases had injury histories that conflicted with the fracture patterns (e.g., a claimed fall from a couch with non-flat fracture characteristics).

The understanding of fracture characteristics and the mechanisms that cause them have significant implications for forensic investigators. The presence of areas of depression, curvilinear, and/or point-of-impact fracture initiation indicated a high likelihood of focal implement impacts, not a flat surface. This information can be pivotal when attempting to determine the mechanism of pediatric cranial blunt force injuries, especially in cases of suspected neglect or abuse.

This project was supported by a grant from the National Institute of Justice, Office of Justice Programs, United States Department of Justice. A77 Pediatric Antemortem Healing Standards Based on Microscopic Analysis of Fractures in Known Forensic Child Abuse Cases

Donna C. Boyd, PhD, Radford University, Forensic Science Institute, PO Box 6939, Radford, VA 24142; Sharon Roller, 56 Harrison Avenue, Waldwick, NJ 07463; and Cliff Boyd, PhD, Radford University, Dept of Anthropological Science, Radford, VA 24142*

The goal of this presentation is to examine the theoretical and anatomical foundations for pediatric antemortem fracture healing and to present microscopically derived healing standards for use in forensic antemortem trauma cases.

This presentation will impact the forensic science community by providing forensic anthropologists and pathologists with more realistic and useable standards for classification and interpretation of forensic pediatric antemortem fractures. This will aid in determination of time-since-injury for these fractures and provide evidence relating to determination of accidental vs. non-accidental etiology for peri-mortem fractures in pediatric death investigations.

This presentation reviews the theoretical and anatomical basis for antemortem healing, particularly in regard to subadults. The process of bone healing from trauma is a complex and dynamic one which does not lend itself well to compilation of finite stages. Numerous phases/stages for antemortem fracture healing have been presented in the medical and forensic literature and are commonly used by forensic anthropologists and pathologists in determination of time-since-injury in pediatric death investigations.[1,2] These assessments heavily influence determinations of accidental vs. non-accidental origin of peri-mortem pediatric fractures. A comparison of these healing phases reveals inconsistencies in their terminology and definition, in part due to reliance on clinical (non-forensic) samples imaged through radiology. Prosser doubts the relevance of these radiological standards to forensic cases because they are based on immobilized fractures in otherwise healthy children examined in a clinical setting.[3] McCormick and Love have called for revised guidelines for antemortem fracture interpretation based on macroscopic forensic samples.[4]

More accurate observation of the antemortem healing process is accomplished through microscopy. In this study, evidence for this healing process is assessed microscopically in a sample of 679 images taken from a digital light microscope, the Keyence VHX-1000 at 5x-200x, representing 48 fractures from five known cases of pediatric death from child abuse. Forty-one of these fractures are present on ribs; the remainder affect long bones and the clavicle. These cases represent the range of the healing process (early to late); in two cases, fairly precise healing times are known or inferred.

These microscopic images are used to illustrate the healing process and develop microscopically based guidelines for bone healing. Key microscopic signatures observed include evidence for acute inflammation, fracture margin rounding, early beginnings of subperiosteal new bone formation, progressive organization of immature fibrous bone leading to bridging and eventual replacement of woven with lamellar bone, resorption of necrotic bone tissue, loss of fracture margins, and advanced signs of remodeling. A series of images showing this bone healing progression is presented.

Based on this analysis, it is proposed that antemortem healing is a continuous process which is not conducive to rigid interpretation using a finite staging system. Stages, as defined, should be used as an interpretive model representing this continuous process.

A78 Understanding the Role of Contact Area in Adult Cranial Fracture Variation

Mariyam I. Isa, BS, Michigan State University, Dept of Anthropology, 354 Baker Hall, East Lansing, MI 48824; Todd W. Fenton, PhD, Michigan State University, Dept of Anthropology, 354 Baker Hall, East Lansing, MI 48824; Patrick E. Vaughan, BS, Michigan State University, Orthopaedic Biomechanics Laboratories, E Fee Hall, Rm 407, East Lansing, MI 48824; and Roger C. Haut, PhD, Michigan State University, Orthopaedic Biomechanics, A407 E Fee Hall, East Lansing, MI 48824*

After attending this presentation, attendees will better understand the relationship between skull-implement contact area, location of fracture initiation, and fracture characteristics in controlled blunt impact experiments performed on adult human heads.

This presentation will impact the forensic science community by helping to clarify the role of implement shape in blunt force impacts, which will inform investigators' interpretation of adult cranial trauma.

The purpose of this presentation is to present new data on shaped impact experiments with adult human heads and to examine contact area between the cranium and an impacting surface and its effect on fracture initiation and fracture characteristics.

Seven unembalmed adult male heads were hit in a series of controlled blunt impact experiments, according to a protocol discussed previously.[1] Impacts were delivered to the center of the right parietal using various shaped implements. These included two flat (3" diameter and 1" square) and two curved (2" diameter hemispherical and 1" diameter spherical) aluminum impactors. High-speed photography captured fracture initiation and propagation in these experiments.

Contact area data was recorded for each impact experiment. Pressurestat contact paper was laid onto the center of the parietal and an impact was delivered at a pre-failure level. The resulting contact area impression was measured using digital calipers. This procedure was repeated ten times per specimen-implement pair to obtain average contact area. Additionally, one specimen was Computed Tomography (CT) scanned and computational Finite Element Analysis (FEA) was performed using Abaqus/CAE standard software to model the effect of contact area on maximum principal stresses.

The results showed that implement shape influences contact area. Significant differences in average contact area were recorded between the 1" spherical (2.88±1.02mm^2), 2" hemispherical (9.72±2.42mm^2), and 3" flat (39.38±13.89mm^2) implements. In impacts with two different specimens, the 1" flat implement produced significantly different contact areas (12.78±8.51mm^2 vs. 58.29±9.90mm^2). This indicated the importance of cranial curvature; an impact with the same implement results in a smaller contact area on a more curved cranial surface than a less curved surface.

Contact pressure generated under the Point Of Impact (POI) varied directly with contact area and corresponded with location of fracture initiation and fracture type produced. The 1" spherical implement generated the smallest contact area and highest pressure (2068±633MPa). This was the only impact to produce depressed fracture. Contact pressure in the 2" hemispherical impact was significantly lower (796.6±221MPa). High-speed photography showed that this impact resulted in a POI-initiated linear fracture, followed by a curvilinear fracture near the POI. Pressure in the 3" flat impact was significantly lower than .in either curved impact (232.3±66.4MPa). In this impact, a linear fracture initiated peripherally rather than at the POI.

When contact area was large, an impact with the 1" flat implement generated pressure statistically similar to the 3" flat impact (207.9±34.4MPa) and produced a similar pattern of fracture (peripheral-linear). When contact area was small, an impact with the 1" flat implement generated pressure statistically similar to the 2" hemispherical impact (558.3±308.9MPa). In this case, fracture also initiated at the POI.

Computational modeling helped explain the fracture data. FEA models showed that a large contact surface produced low stresses at the POI, but high tensile stresses at the cranial sutures; this resulted in the initiation of linear fracture peripheral to the POI. At the same energy, a small contact area produced higher stresses and failure at the POI, potentially with depression.

The results of this study suggest contact area, more precisely than implement shape, may explain variation in fracture patterns observed in adult cranial impacts. At similar energy levels, contact area determined the pressure generated under the POI. Contact pressure, in turn, influenced fracture initiation (POI vs. peripheral) and fracture type (depressed vs. linear). Contact area decreased with decreased implement size, but also with increased cranial curvature. These experimental results may help explain differences in cranial fracture patterns observed between individuals or in impacts to different areas of the skull.

Blunt Force Trauma, Cranial Fracture, Trauma Biomechanics

A79 Dismemberment Injuries: The Contribution of Bone and Soft Tissue Histology

Tania Delabarde, PhD, Institut de Médecine légale, 11 rue Humann, STRASBOURG 67085, FRANCE; Catherine Cannet, 11 Rue Humann, Strasbourg 67065, FRANCE; Annie Geraut, MD, 11 Rue Humann, Strasbourg 67000, FRANCE; Marc Taccoen, MD, Institut Médico-Légal, 2 Place Mazas, Paris 75012, FRANCE; Bertrand P. Ludes, MD, PhD, Institut Medico- Legal, 2 Place Mazas, Paris 75012, FRANCE; and Jean-Sébastien Raul, 11 Rue Humann, Strasbourg, AE 67085, FRANCE*

After attending this presentation, attendees will better understand the potential of histological analyses on bone and soft tissues from dismembered victims.

This presentation will impact the forensic science community by providing three cases of documented dismemberment injuries that exemplify the contribution of histology to direct the investigation and bring evidence to the courtroom.

Dismemberment, the intentional separation of body segments, is known to be one of the major postmortem activities performed by humans on the remains of others. The victim's body is the foremost source of evidence and attempts to dispose of remains may inhibit identification and destroy links with the perpetrator, the crime scene, and the events leading up to death. Three forensic cases of dismembered victims are presented to discuss relevant autopsy and anthropological and histological findings.

Case Study 1: Dismembered body segments of a young adult male placed in three plastic bags were recovered in the street by a doorman next to a garbage area. During the autopsy, a great number of stab wounds were found and cause of death was determined as multiple stab wounds to the chest (cardiac and pulmonary laceration). The victim also sustained saw marks associated with complete separation at the level of the cervical spine, upper limbs, and lower limbs. Bone sections and cutaneous margins were removed for cut marks analysis and histology. Dismemberment was suspected to be postmortem as no evidence of hemorrhagic infiltration was observed during autopsy and was later confirmed by histopathology results. Numerous false starts and kerfs exhibited characteristics consistent with a power saw. Histomorphometric analyses of bone and soft tissue revealed the presence of exogenous particles (silicon carbide) that belong to a specific power saw blade. This information was crucial for the determination of the tool type used by the perpetrator.

Case Study 2: The remains of a saponified dismembered body from a young female were exhumed from a house basement. Only the lower limbs sustained dismemberment injuries with the complete separation of legs and feet. Bone segments were retained for both anthropological examination of cut marks and histological analysis. Kerf walls exhibited blue particles that were observed macroscopically and microscopically as potential paint residue. Anthropological and histological findings were relevant to identify class characteristics of the offending instrument: a hand saw with a blue-painted blade was finally recovered by police officers in the house of the perpetrator, who confessed to the murder and dismemberment of the victim.

Case Study 3: The saponified body of an adult male was exhumed from a shallow grave. The head was completely severed from the trunk at the level of the second and third cervical vertebra. Autopsy findings were consistent with sharp force injuries at the level of the neck with the use of a blade instrument. Bone and soft tissue were retained for examination of cut marks and histological analysis. Bone examination confirmed the presence of incisions on both vertebrae consistent with sharp force trauma. The presence of exogenous particles was determined on bone and soft tissue samples; their physical characterization was different from geological features from the grave location but consistent with the place of events described by perpetrators.

These three case studies illustrate that bone histology offers great potential for augmenting the investigation and is not limited to age estimation or bone remodeling. Soft tissue and bone samples from traumatic injuries should be microscopically examined as histomorphometric findings are complementary with forensic examination data and could sometimes provide key elements for the investigation.

Histology, Dismemberment, Forensic Anthropology

A80 Evaluating Timing of Injury in Central Florida: Examining the Transition of Fracture Characteristics From Wet to Dry in Long Bones

Ashley Green, MA, 1219 Dowden Street, Charleston, SC 29407; and John J. Schultz, PhD*, University of Central Florida, Dept of Anthropology, 4000 Central Florida Boulevard, HPH 309, Orlando, FL 32816*

After attending this presentation, attendees will better understand the transition of intrinsic properties of bone from wet to dry. This presentation will focus on the timing of injury in the postmortem period in order to fill a gap in the literature regarding the time frame in which bone transitions from wet properties to dry properties in the Central Florida environment by examining fracture characteristics.

This presentation will impact the forensic science community by discussing the timing of the transition of intrinsic properties of bone from wet to dry. Fracture characteristics such as fracture angle, fracture surface, and fracture outline will be discussed in terms of wet and dry characteristics. This will aid the forensic community in differentiating between peri-mortem and postmortem trauma in the elastic peri-mortem period.

Differentiating between peri-mortem and postmortem fractures can be difficult when bone retains fresh characteristics in the Postmortem Interval (PMI). As a result, it is important to conduct research that investigates the timing of the injury in the postmortem period by observing fracture characteristics created at known intervals.[1-4] Investigation into the timing of injury was undertaken over a 14-week time period in Central Florida. By fracturing bones using a custom impact device, specific morphological characteristics typically used in trauma analysis were able to be analyzed: fracture angle, fracture surface, and fracture outline.[1-4] Long bones of pigs (*Sus scrofa*) (N=140) were placed in two outdoor microenvironments: full sun (Group A) and full shade (Group B). Five bones were collected from each microenvironment weekly and subsequently fractured. Additionally, a control group of five fresh bones was fractured immediately to simulate peri-mortem trauma.

Analysis of fracture characteristics was conducted using a standardized protocol modified from previous studies.[1-4] Statistical analyses were performed to investigate the relationships between the variables. The statistically significant results of the Chi-square analysis for the entire data set comparing fracture angle and fracture outline (p=0.000), fracture angle and fracture surface (p=0.003), and fracture outline and fracture surface (p=0.000) indicate that the variables are likely dependent upon one another; however, when microenvironment was considered, the results indicate that fracture angle and fracture outline are likely independent of one another for Group B (p=0.080). Analysis of Variance (ANOVA) testing was conducted for the entire data set, as well as considering microenvironment, using time (the PMI) as a dependent variable. The results denote statistically significant relationships between fracture angle and PMI (p=0.001), fracture surface and PMI (p=0.000), and fracture outline and PMI (p=0.006); however, when environment was considered, the results denote no significant relationship between fracture outline and PMI for Group A (p=0.154). The results of this study indicate a discernable shift in the timing of occurrences of dry characteristics as PMI increases, with a transitional period identified around weeks 5 to 9. Wet characteristics were observed into the 13th week; however, dry characteristics were seen within two weeks postmortem Additionally, statistical analyses indicate that the environment in which bones are deposited has a significant effect on fracture surface and outline as PMI increases.

These results suggest that it is possible to distinguish wet from dry fracture characteristics in Central Florida earlier than previously reported.[1-4] Fracture surface and fracture outline were the most useful characteristics for evaluating the transition from wet to dry. Group B exhibited dry characteristics earlier than Group A, indicating environmental factors are regionally specific and specific to microenvironments. The use of taphonomic models that are regionally specific and standardized protocols for scoring fracture characteristics provides increased accuracy in estimating timing of injury.

Forensics, Fracture, Trauma

A81 A Test of the Transition Analysis Method for Estimating Adult Age-at-Death

Jessica L. Campbell, MS, 2507 15th Street, Troy, NY 12180; and Stephen P. Nawrocki, PhD, University of Indianapolis, Dept of Biology, 1400 E Hanna Avenue, Indianapolis, IN 46227-3697*

After attending this presentation, attendees will better understand the effectiveness of Transition Analysis (TA) and ADBOU software compared to other well-known age estimation methods for skeletonized remains.

This presentation will impact the forensic science community by providing a rigorous validation test of TA and by identifying the limitations and advantages of various age estimation methods.

Several problems inherent to most age estimation methods include the tendency to overestimate the ages of younger individuals and to underestimate the ages of older individuals, to lump the elderly into an umbrella category of ">50 years," and "age mimicry," or the tendency of a method to produce age estimates that mirror the age distribution of the collection on which the method was developed. Milner's and Boldsen's TA was developed to address and resolve these problems.[1] The method uses Bayesian statistics in tandem with a modified "component" scoring system to produce an age estimate that reflects a decedent's age at transition. The method's software interface, ADBOU, draws from one of two known prior population distributions (forensic and historic hazards) that are preloaded and unalterable. TA scores a number of different components for three skeletal indicators: the Pubic Symphysis (PS), the Auricular Surface (AS), and the Cranial Sutures (CS). TA can therefore be used with incomplete or fragmented remains.

The present study's primary goal is to test the accuracy of TA and ADBOU against traditional "phase" methods commonly used for the same three skeletal indicators: Suchey-Brooks' (PS), Osborne et al. (AS), and Nawrocki (CS). The hypothesis that TA is more effective in older age ranges than traditional methods was evaluated by calculating inaccuracy and bias by decade; Spearman's rho evaluated whether component scores are correlated with actual age better than phase scores; and the effects of continent of origin and ancestry on prediction error were evaluated with Analysis of Covariance (ANCOVA).

This study sample consisted of 147 modern adult males with documented ages at death, drawn from the Pretoria Bone Collection in South Africa (n=72) and the Bass Donated Collection in Tennessee (n=75). Scoring was conducted blind without reference to the actual age of the decedent. Each skeleton was scored using the three traditional phase methods as well as with the three TA component methods. Target age estimates and 95% prediction intervals were obtained for each male using the traditional method's published tables and ADBOU's algorithms for the TA data. Furthermore, summary age estimates were calculated by averaging the results of the three traditional methods, to compare with the corrected age calculated by ADBOU.

Mean prediction error (inaccuracy) is always significantly lower for the three traditional methods than for the three TA component methods, and averaging the three traditional methods produces the lowest mean error in the study (12.5 years, compared to 17.1 years for TA). While average bias was always significantly lower for the three TA component methods, the summary age provided by ADBOU suffers from considerable bias, indicating there may be a problem with the software's algorithm. Evaluation of the older age categories indicates that TA does not provide any clear advantage over traditional methods, although TA does seem to produce slightly more accurate estimates for younger individuals. Spearman's rho shows that component scores, taken individually or summed, are not more highly correlated with age than traditional phase scores. ANCOVA results indicate that residuals from the traditional methods were not influenced by ancestry or continent of origin, while the TA residuals were. These results indicate that: (1) while TA does display lower prediction bias, it does not perform as well as traditional methods with respect to inaccuracy, and therefore, in forensic settings, the traditional methods are preferred; (2) age estimation is more accurate when multiple indicators are averaged; and, (3) despite their lower accuracy, the cranial sutures seem to stabilize the other indicators, offsetting the tendency for the pubic symphysis and auricular surface to underestimate age.

Age Estimation, Transition Analysis, Biological Profile

A82 Examining the Accuracy of Age Estimates From New Histological Sampling Strategies at the Femoral Midshaft

Timothy P. Gocha, PhD, The Ohio State University, 1645 Neil Avenue, 279 Hamilton Hall, Columbus, OH 43210; Sam D. Stout, PhD, Ohio State University, Dept of Anthropology, 4034 Smith Laboratory, Columbus, OH 43210-1106; and Amanda M. Agnew, PhD, The Ohio State University, 279 Hamilton Hall, 1645 Neil Avenue, Columbus, OH 43210*

After attending this presentation, attendees will understand the spatial variation present in the distribution of intracortical remodeling events throughout the entirety of the femoral midshaft and the importance of selecting Regions Of Interest (ROI) for developing new histological aging methods.

This presentation will impact the forensic science community by introducing new sampling strategies for the quantification of histological remodeling that can be used to estimate age and further demonstrating these age estimates to be highly accurate throughout the adult life span.

As a complement to macroscopic aging methods, or when necessary macroscopic elements are damaged/absent, age can be estimated through histological examination of remodeling events in cortical bone. During the past half century, the femoral midshaft has been the most commonly employed site for histological studies; however, a consensus is still lacking on where to best quantify remodeling, as different methods employ various ROIs that differ in size, number, and location. To address this knowledge gap, this study employed Geographic Information Systems (GIS) software to digitally map all remodeling events (intact and fragmentary osteons and resorptive bays) across the entirety of the femoral midshaft. Patterns in the spatial distribution of remodeling were then examined to identify which region(s) of the femoral cortex produce the most accurate age estimates.

Thirty complete cross-sections from modern cadaveric femora were used, 15 of each sex, ranging from 21 year to 97 years of age (mean=58.9; Standard Deviation (SD)=22.1 years), with both sexes having similar age distributions. Each sample was photographed under polarized light and seamless cross-sectional images were imported into arcGIS® v10.1. Polygon features were created to overlay cortical areas and all remodeling events (n=230,870) were identified and digitally annotated with point features. A total of ten different sampling strategies were employed, each subdividing the entire cortex in a different manner. Osteon Population Density (OPD) was calculated by summing all remodeling events within an ROI and dividing by its area.

Statistical analyses were performed in the Statistical Package for the Social Sciences (SPSS) 21. OPD values were normally distributed for each ROI, and Multivariate Analysis of Covariance (MANCOVA) analyses revealed that OPD was not significantly different between sexes for any ROI, allowing the combination of male and female data for further analyses. Paired t-tests revealed OPD calculations were not statistically different between observers. Stepwise linear regression was used to determine which ROIs from each sampling strategy were most useful in estimating age. To further evaluate the performance of the resulting predictive models, jackknife age estimates were generated by removing an individual from the sample, recalculating the regression model, and then estimating the age of the individual not included in the model; this was done iteratively for all individuals. The accuracy of these estimates was analyzed through measures of bias and inaccuracy.

Results indicate the two most promising sampling strategies are dividing the femoral cortex into Anterior, Posterior, Medial, and Lateral (APML) quadrants separated into periosteal, middle, and endosteal thirds, and also APML octants separated into thirds. Stepwise regression selected four ROIs for each method, primarily in the lateral and anterolateral regions of the cortex, and spread between all depths of the cortex. The resulting model for the APML quadrants by thirds explains more than 90% of the variation in age (adj. R^2=0.907, p=0.000) with a standard error of 6.73 years, while the APML octants by thirds explained more than 93% of the variation in age (adj. R^2=0.931, p=0.000) with a standard error of 5.82 years. Jackknife age estimates from both models were very promising, with average differences between estimated and known age (bias) being less than one year and average absolute differences between estimated and known age (inaccuracy) being less than six years. Further, individuals in their 90s had bias and inaccuracy measures of less than seven and four years for the quadrants and octants methods, respectively. Such accuracy in age estimation, even into the tenth decade of life, demonstrates that this new method for histological aging considerably outperforms more traditional macroscopic methods of aging in older individuals. Considering increasing life expectancies, this research has great promise in providing forensic anthropologists with a tool to accurately age elderly individuals.

Age Estimation, Skeletal Histology, Forensic Anthropology

A83 Increasing Precision in Age Estimation From the Female Os Pubis: A Composite Technique With >80% Accuracy to Within Ten Years of Actual Age

Janamarie Truesdell, MSc, University of Oxford, School of Anthropology and Museum Ethnography, 51/53 Banbury Road, Oxford, Oxfordshire OX2 6PE, UNITED KINGDOM; Andreas Duering, MA, MS, Oxford University, School of Archaeology, 36 Beaumont Street, Oxford, Oxfordshire OX1 2PG, UNITED KINGDOM; and Nicholas Márquez-Grant, PhD, Cranfield University, Cranfield Forensic Institute, Defence Academy of the United Kingdom, Shrivenham SN6 8LA, UNITED KINGDOM*

After attending this presentation, attendees will be familiar with the implementation of a new, continuum-based technique for estimating age from the female os pubis exhibiting 83.9% precision to within ten years of actual age (Author: 96.5%, Observer 1 (Ob1): 82%, Ob2: 74.9%, Ob3: 82.2%) and a further 67.7% precision to within five years of actual age (Author: 85.9%, Ob1: 56%, Ob2: 66.7%, Ob3: 62.2%).

This presentation will impact the forensic science community by introducing a highly effective, supplementary aging technique to be employed alongside those already in regular use for the estimation of age from the pubic symphysis. Additionally, as it is Computed Tomography (CT) based, this presentation will also add to the growing body of literature advocating for the adoption of proactive medical imaging into biological profiling research, as well as to that of age estimation in the living.

Age estimation from the pubic symphysis continues to be one of the most frequently researched and innovated topics in the field of forensic anthropology. Historically, methodologies have fallen into two distinct paradigms: phased, archetypal "picture-matching" techniques versus equation and weighted variable-based component systems. The methodology introduced by this presentation seeks to bridge this gap by combining the traditional, user-friendly "picture-matching" approach with both component and numbered variable elements and by placing morphological change along a continuum, allowing for variation as well as differences in individual senescence.

The proposed technique, the Truesdell Composite Method (TCM), was developed with the assistance of a mixed British sample of 585 female volunteers, all with verified ages (16 years to 93 years of age) and detailed life histories (gathered by this study in a series of face-to-face interviews cross-referenced with hospital records). In addition to parity, potentially confounding variables such as height, weight, race, activity level, diet, alcohol consumption, tobacco use, medications, infection and/or disease in or around the pelvic area, osteoarthritis and/or osteoporosis, hormone supplementation, and the use of birth control were also taken into account (though none bore any significance on accuracy). For comparison, both left and right pubic bones (volume rendered from CT) were assessed for each individual using the Suchey-Brooks Method for aging the os pubis, the Hartnett Method, and the TCM.[1,2]

Subjects were placed into appropriate Suchey-Brooks ranges an average of 89.4% of the time (86.3%, author excluded), but only 49.4% (49.9%) of the time was the mean within a decade of the actual age and, within that, only 27% (26.9%) of the time was it within five years of the actual age. This is likely a reflection of the sample's propensity toward older individuals (~50% over 65 years). The Hartnett Method fared less well overall, with subjects being placed into appropriate ranges 75.5% (70.4%) of the time but, within the ranges themselves, fared slightly better than Suchey-Brooks with means within ten years of actual age 65.4% (59.6%) of the time and 39.1% (33.2%) within five years. When using the TCM, estimations to within ten years of actual age increased to 83.9% (79.7%) and to 67.7% (61.6%) within five years. For Suchey-Brooks, this constitutes a 34.5% (29.8%) increase in precision to within ten years of the actual age and a 40.7% (34.7%) increase in precision to within five years. For the Hartnett Method, precision to within ten years was increased by 18.5% (20.1%) and to 28.6% (28.4%) within five years.

The proposed technique was not designed to replace established methodologies, whose reliability and efficacy are not in question. Instead, by bringing together the best and most effective aspects of two disparate paradigms, it seeks simply to increase precision, and therefore practitioner confidence (especially regarding older individuals), within the existing framework of the methodologies themselves.

A84 Apophyseal Ossification of the Iliac Crest in Forensic Age Estimation: New Standards for Modern Australian Subadults Using Computed Tomography

Nicolene Lottering, BS, Queensland University of Technology, School of Biomed Sci, Faculty of Health, 2 George Street, Gardens Point, Brisbane, Queensland 4001, AUSTRALIA; Mikaela S. Reynolds, MSc, Level 5 Q Block, 2 George Street, Gardens Point, Brisbane, Queensland 4001, AUSTRALIA; Donna M. MacGregor, MSc, Queensland University of Technology, School of Biomedical Sciences, Faculty of Health, Gardens Point Campus, Brisbane, Queensland 4001, AUSTRALIA; Maree T. Izatt, Queensland University of Technology, 2 George Street, GPO Box 2434, Brisbane, Queensland 4000, AUSTRALIA; Caroline Grant, PhD, Queensland University of Technology, Paediatric Spine Research Group, O Block, Level 4, Rm 413, Gardens Point Campus, Brisbane 4001, AUSTRALIA; Clayton Adam, PhD, Queensland University of Technology, Paediatric Spine Research Group, O Block, Level 4, Rm 413, Gardens Point Campus, Brisbane 4001, AUSTRALIA; and Laura S. Gregory, PhD, Queensland University of Technology, School of Biomedical Sciences, Gardens Point Campus, Brisbane, Queensland 4001, AUSTRALIA*

After attending this presentation, attendees will: (1) appreciate recalibrated population-specific age standards for Australian subadults based on the Risser Sign, and the implication of idiopathic scoliosis on the derivation of age estimates; and, (2) become familiar with ontogeny of the iliac crest apophysis using 3D reconstructions of Multi-Slice Computed Tomography (MSCT) data.

This presentation will impact the forensic science community by demonstrating the potential of a contemporary MSCT database of abdomino-pelvic scans to assess the currency of methods such as the Risser Sign for clinical age assessment of maturation milestones.[1] This presentation discusses and surmounts limitations associated with conventional radiographs by utilizing MSCT Multi-Planar Reformatted (MPR) and Volume Rendered Reconstructions (VRR) to formulate Australian standards for forensic age estimation, based on excursion and fusion of the iliac crest apophysis.

Accurate age-at-death estimation of skeletal remains represents a key element in forensic anthropology, while age estimates of living individuals are of increasing importance for forensic medicine, considering the increase in transnational migratory movements. The age of criminal responsibility under Australian federal law is ten years of age, while *doli incapax*, the maximum age of presumption against criminal responsibility constitutes 14 years of age. Wittschieber et al. contend that the Risser Sign is suitable for forensic age estimation, especially the demarcation of the 14th year of life.[2] Combined with other roentgenographic indices of maturation, excursion of the iliac crest is used to estimate remaining growth potential and the likelihood of progression in patients with adolescent idiopathic scoliosis, which influences clinical intervention decisions such as bracing or surgery.

The present study seeks to determine whether the Risser Sign, used routinely for assessing iliac crest maturity in scoliosis patients, is suitable for age estimation of subadults, particularly in cases claiming *doli incapax*. The sample composes MSCT abdomino-pelvic Digital Imaging and Communications in Medicine (DICOM) data (0.5mm/0.3mm) acquired from 255 'trauma-screened' Australian individuals aged 6-25 years, admitted to Brisbane children's hospitals between 2007 and 2014. The Risser US six-stage system was employed to score ossification of the iliac crest. Transition analysis was applied to elucidate maximum likelihood estimates between maturational states; robust age parameters were established using a Bayesian statistical approach, with an MCMC sampler. Volume averaging reconstructions of DICOM datasets, using a coronal reformat were employed to create pseudoradiographs for Risser scoring of trauma-screened children. Standards for Queensland idiopathic scoliosis patients (females: 436, males: 95) aged 6 years to 23 years were derived from clinical databases comprising conventional surveillance radiographs, including the pelvis and analytic data (e.g., Risser Sign, Cobb Angle) from a scoliosis progression study performed by the Paediatric Spine Research Group between 1995 and 2007. Comparisons of maximum likelihood estimates demonstrate no significant developmental anomalies in iliac crest maturation associated with idiopathic scoliosis. Age-at-transition for apophyseal appearance corresponds to 12.99±1.3 years in females and 13.87±0.94 years in males. Posterior distributions signify complete appositional growth (Risser 4) at 15.06 (95% CI:13.5-16.7) years and 15.99 (95% CI:14.9-17.0) years in females and males, respectively, an important demarcation stage for scoliosis management. Lack of discriminant power between stages 2-4 demonstrate that the 14th-year legal demarcation cannot reliably be determined in females using this method on conventional radiographs.

Risser grading on MPR and VRR models of Australian subadults reveals interesting anatomical deviations, highlighting flaws in the ossification progression stated by Risser. Appearance of the apophysis is witnessed 6 months to 12 months earlier in MSCT than pseudoradiographs. Circumventing radiographic limitations such as superimposition, a modified eight-stage MSCT scoring-tier was developed for appearance and fusion of the apophysis, demonstrating origins from three secondary ossification centers. Complete fusion/obliteration occurs between 18.4 years to 19.7 years in males and 19.3 years to 20.3 years in females; indicating secular change in Australian children in contrast to anthropological standards of Coimbra individuals and the 23-year demarcation by Webb and Suchey.[3,4]

The contributions of this original research are extensive. Caution in the derivation of ossification standards from conventional radiographs is advised, with conflicting timings and morphological progression to MSCT assessment. Retrospective clinical data acquisition provides the ideal catalyst for the advancement of anthropological subadult research, demonstrated by the construction of refined, Australian standards for age estimation of the current milieu. Bayesian posteriors of the MSCT scoring-tier demonstrate successful *doli incapax* age estimation for utility in criminal proceedings.

Age Estimation, Subadult, Iliac Crest Apophysis

A85 DNA Methylation Markers as a Novel Tool for Age-at-Death Estimation in Teeth

Sara C. Zapico, PhD, Smithsonian Institution, Dept of Anthropology, NMNH, MRC 112, 10th & Constitution Avenue, NW, Washington, DC 20560; Bram Bekaert, PhD, University of Leuven, University Hospitals Leuven, Dept of Forensic Medicine, Leuven, BELGIUM; Aubeline Kamalandua, MS, University of Leuven, Forensic Biomedical Sciences, Department of Imaging and Pathology, Leuven 3300, BELGIUM; Wim Van de Voorde, MD, University of Leuven, University Hospitals Leuven, Dept of Forensic Medicine, Leuven, BELGIUM; and Ronny Decorte, PhD, University of Leuven, University Hospitals Leuven, Dept of Forensic Medicine, Leuven, BELGIUM*

After attending this presentation, attendees will consider the possibility of using DNA methylation markers for age-at-death estimation in teeth as an alternative to classical anthropological methods.

This presentation will impact the forensic science community by introducing a novel, innovative, and accurate approach for age-at-death estimation based on the current state-of-the-art research on aging.

Age estimation represents one of the fundamental parameters in forensic anthropology in creating the biological profile toward the correct identification of an individual. This parameter is particularly important in mass disaster scenarios where skeletons are often incomplete, which makes the correct identification of the victims difficult. Teeth are frequently preserved long after all other tissues have disappeared and are often used to estimate characteristics like age at death.

There are several approaches to age estimation based on dental development. In forensic anthropology, the Lamendin technique and its variants are non-invasive methods of age-at-death estimation; however, these methods can only be applied to single-rooted teeth and their accuracy is not guaranteed due to differences in population-specific references. New methodologies for age estimation are based on the natural process of aging, which causes alterations of tissues and organs on different biochemical levels. Recently, it has been discovered that one of these alterations are changes in DNA methylation patterns. In fact, some studies identified and correlated DNA methylation biomarkers with age in blood samples. Although these studies were mainly developed in blood samples, these are potentially interesting in forensic identification because they could help to improve the estimation of age at death.

Since teeth are the hardest tissues of the human body and one of the most abundant types of biological remains available in forensic cases, the goal of this study is to evaluate the potential usefulness of DNA methylation biomarkers for age-at-death estimation in dentin and assess the reliability and accuracy of this methodology in this tissue.

Twenty-nine healthy erupted third molars were collected from dental clinics in Spain (aged 19 years to 70 years). The Smithsonian Institution's ethical committee approved all procedures related to experimentation with human subjects. The teeth were cleaned and the enamel and cementum removed. The dentin was isolated, mechanically ground, and divided in aliquots of 200mg each. Then dentin was submitted for DNA extraction and quantification; 200ng of genomic DNA was bisulfite converted and later amplified by Polymerase Chain Reaction (PCR) for the following genes: ASPA, PDE4C, EDARADD, and ELOVL2. To analyze DNA methylation levels of five CpG sites in these genes, pyrosequencing was performed.

After analyzing pyrosequencing results, a multivariate linear regression model was selected from all methylation sites present in the pyrosequencing assays of ASPA, PDE4C, ELOVL4, and EDARADD by using the step function in R, which selects the model that explains most of the observed variance, predicting age with an adjusted R2 of 0.74 and a Mean Absolute Deviation (MAD) of 4.84 years (p-value <0.001).

This research is the first to explore age-associated methylation in teeth. The findings from this study provide a new quantitative tool for estimating age at death which, in combination with traditional age markers, could improve identification accuracy in forensic cases. Future research may be able to expand on these results, identifying new markers through whole genome CpG studies, using different types of teeth and extending the age range.

Age-at-Death, DNA Methylation, CpG Marker

A86 A Novel Method for Recording Palate Shape in the Estimation of Ancestry

Christopher A. Maier, MA, University of Nevada, Reno, 1664 N Virginia Street, Ansari Business 512, Reno, NV 89557*

After attending this presentation, attendees will learn a new method for scoring palate shape with standardized descriptions. This new method can be used in conjunction with other methods of ancestry estimation to refine the biological profile. Additionally, attendees will gain an understanding of the utility of palate shape as an indicator of ancestry.

This presentation will impact the forensic science community by expanding the traits available for the forensic assessment of ancestry and by providing a standardized means by which to assess palate shape, a trait traditionally scored based on shape variables with somewhat misleading names.

Palate shape has been in use as an indicator of ancestry since 1931 when Hooton included it on the Harvard Blanks list of traits.[1] Since then, it has been included in multiple lists on ancestry-related traits.[2-5] Although a well-established trait, no definition exists of what precisely should be assessed, and there is little agreement as to what shapes are associated with which ancestries. Hooton referred to White, Black, and Asian/Native American palates as pinched, narrow, and wide, respectively, while Krogman and Işcan refer to the palates of the same groups as narrow, wide, and intermediate, and Gill calls them parabolic, hyperbolic, and elliptical.[1-4] The subjectivity inherent in recording this trait has left some practitioners questioning the utility of palate shape as an effective indicator of ancestry.[6] Previous work found that by using digital representations of the palates, individuals were assigned to the correct ancestry 68% of the time, which is more than twice as good as chance; however, the methods outlined in that study require the use of a digitizer and statistical software not available to all forensic anthropologists.

The present study defines a novel rank scale to assess palate shape. For this research, palate shape is defined as the overall trend in shape of both the dental arcade and the underlying alveolar bone and was recorded according to five ordinal character states. States 1, 3, and 5 correspond to the traditional elliptical, parabolic, and hyperbolic shapes, respectively, while states 2 and 4 represent transitional shapes. This newly defined method was then tested on a sample of individuals of known ancestry (n=146).

Data were collected on individuals housed at the Pima County Office of the Medical Examiner, the Donated Collection at the Forensic Anthropology Center at Texas State, and the Donated Collection curated by the Forensic Anthropology and Computer Enhancement Services (FACES) lab at Louisiana State University. Palate shape was recorded on individuals of White, Black, Asian/Native American, and Hispanic ancestry using this new method. Intra-observer error was assessed using weighted Cohen's Kappa (K=0.55, p<0.001), which indicates that there is moderately good agreement as outlined by Landis and Koch, and that this agreement score is significantly different from that expected from chance.[7] A frequency table of the distribution of each score by ancestry was created, and Chi-square analysis indicated that significant differences in palate shape exist between ancestry groups (χ^2=59.9974, p<0.001). A post-hoc test of the Chi-square results indicated that all pair-wise comparisons of ancestry groups were significantly different (p<0.05) with the exception of the Black vs. Asian/Native American comparison (p=0.1282), which was likely not significant due to insufficient sample size.

The adoption of this scale for recording palate shape has initially shown that it is successful at distinguishing ancestral groups and can be useful as a skeletal indicator of ancestry. The use of this scale will provide a standard means of recording palate shape that does not require the use of special equipment, therefore making it useful for a broader range of anthropologists. This new scoring method can then be added to the suite of methods available to forensic anthropologists to estimate ancestry.

Forensic Anthropology, Ancestry, Macromorphoscopics

A87 Ancestral Variation in Orbital Rim Shape: A 3D Pilot Study

Katie M. Rubin, MS, CA Pound Human ID Laboratory, PO Box 103615, Gainesville, FL 32610; and Valerie DeLeon, PhD, University of Florida, Dept of Anthropology, Turlington Hall, Rm 1112, Gainesville, FL 32611*

After attending this presentation, attendees will better understand how curviplanar relationships along the orbital rim may inform ancestry analyses and may begin to evaluate orbital shape in 3D.

This presentation will impact the forensic science community by highlighting the need to investigate non-metric traits more rigorously as forensic anthropology moves into the future.

Traditional non-metric methods of ancestry assessment posit that orbital shape can be used to help discriminate among broad ancestral groups.[1,2] These claims are based upon visual assessment of crania (rendering them prone to high inter- and intra-observer error) and are supported by limited frequency data. Recently, a handful of studies have used geometric morphometrics to reassess ancestral differences in 2D orbital shape.[3,4] A study by Urbanová assessed ancestral variation in orbital shape in three dimensions; however, this study looked at differences between Czech and Portuguese populations only.[5] To this study's knowledge, no published studies assess 3D orbital variation for the three broad ancestral groups commonly discussed in United States ancestry assessment literature. The results of this pilot study suggest a need to fill this research gap, especially as the demand for forensic scientists to offer statistical support for their methods increases.

The cranial sample used in this study is part of the evidentiary collection of the C.A. Pound Human Identification Laboratory at the University of Florida. The study sample consists of 9 individuals of primarily Asian ancestry (broadly defined), 10 individuals of primarily African ancestry, and 12 individuals of primarily European ancestry.

All crania were digitized using a MicroScribe®. Bregma, nasospinale, and staphylion were digitized to establish a homologous midline plane. Each orbital rim was divided into upper (vault) and lower (facial) curves using dacryon and frontomalare orbitale as homologous start and end points and digitized using the MicroScribe® scan setting. To minimize intra-observer error, each curve was digitized three times. Curve coordinates for each trial were resampled (10 semilandmarks for the upper curve; 15 for the lower) and subjected to sliding semilandmark analysis within specimens using IMP8 Simple3D ChainMan3D executable software. The mean orbital shape for each specimen was calculated with Simple3D. All mean shapes were re-slid together in ChainMan3D to minimize arbitrary differences among specimens. The final configurations underwent generalized Procrustes analysis. Principal Components Analysis (PCA) was conducted using IMP8 ThreeDPCA8, which generates Principal Components (PCs) based on partial warp scores.

A one-way Multivariate Analysis of Variance (MANOVA) was used to assess the effect of ancestry on the first eight PCs, which account for more than 80% of the total inter-individual variation in orbital shape (p=0.0003). The results of the MANOVA appear to be driven by the first two PCs (47.2% of total variation). Post hoc ANOVAs indicated a significant effect of ancestry on PC1 (p<0.0001) and PC2 (p=0.0026). PC3 through PC8 did not provide any additional discrimination. Centroid size did not differ significantly between the ancestral groups and did not have a significant effect on either PC1 or PC2 scores. Differences among groups are driven primarily by curviplanar relationships between contralateral orbital rim margins.

"European" orbits are distinguished from both "African" and "Asian" orbits along PC1. "European" orbits display more marked folding of the orbit in the sagittal plane; the lateral and medial orbital margins extend further posteriorly relative to the superior margin, and the superior orbital rim projects more anteriorly relative to the inferior border.

In contrast, "African" and "Asian" orbits are distinguished from each other along PC2, which describes relationships between the lateral and medial orbital margins. The lateral margin of "African" orbits lies further posteriorly relative to the medial margin when compared to the relatively co-planar "Asian" orbital rims.

The traditional anterior view of the orbits shows apparent differences based on ancestry; however, these are strongly influenced by the curviplanar relationships described above and prone to error based on orientation of the skull.

The study is severely limited by the size and nature of the sample analyzed, but may help guide future studies of a similar nature. Together, this study and that of Urbanová suggest that curviplanar relationships may be the most ancestrally informative aspect of orbital rim shape. If future studies address the limitations of these studies, they may provide valuable insight into, and statistical support for, the use of non-metric ancestry assessment in forensic analyses.

Ancestry, Orbit, Morphometrics

A88 Missing Data Imputation Methods Using Morphoscopic Traits and Their Performance in the Estimation of Ancestry

Michael W. Kenyhercz, PhD, University of Tennessee, 250 S Stadium Hall, Knoxville, TN 37996; Nicholas V. Passalacqua, PhD, 1559 Mount Vernon, East Lansing, MI 48823; and Joseph T. Hefner, PhD, Michigan State University, Dept of Anthropology, 355 Baker Hall, East Lansing, MI 48824*

After attending this presentation, attendees will understand the effects of missing data imputation on the estimation of ancestry from the human cranium using morphoscopic variables.

This presentation will impact the forensic science community by demonstrating which missing data imputation methods have the highest accuracy when working with morphoscopic traits for the determination of ancestry.

Missing data is an inherent problem in biological anthropology due to the fragile nature of osseous material; these issues are compounded in forensic anthropology as remains in forensic contexts are often subjected to peri-mortem trauma or taphonomic alterations that damage or destroy bony morphology. Often in cases with missing data, the variables in question are just excluded from analysis; however, the avoidance of analytical processes when missing data are present have the potential to significantly decrease the ability to reliably estimate aspects of the biological profile, limiting the number of variables used or decreasing the power of the estimations.

While different methods function differently, the goal of missing data imputation methods is to accurately estimate the missing values, using the other observed values. Unfortunately, the analysis of datasets with missing values receives little attention and listwise deletion is the most common form of handling cases with missing values; however, this is often not possible in forensic anthropology, where the entire sample is a single case that may present varying levels of missing data. Because of this, the ability to accurately impute missing data in forensic anthropology is paramount. The goal of this project is to quantify the accuracy of morphoscopic data in conditions with moderate (25%) and severe (50%) amounts of missing data.

Four data imputation techniques were selected to examine which of the missing data imputation methods performed best: Hot-Deck, Iterative Robust Model (IRMI), K nearest-neighbor (kNN=5), and the variable medians. A subset of Hefner's Macromorphiscopic Databank was used. The full sample consisted of 688 individuals from three population groups (Black=292, Hispanic=186, and White=210). Six commonly used cranial macroscopic variants were scored in accordance with Hefner, and Hefner and Ousley.[1,2] Two versions of the dataset were then created wherein values were randomly deleted from each variable so that 25% and 50% of the data were considered missing. The same data subsets were used for each of the imputation techniques, and the efficacy of each technique was based on absolute agreement using the Intra-Class Coefficient (ICC). Correct classification rates and Mahalanobis D^2 values were calculated for the original dataset with actual measures and each of the imputed datasets in order to examine the effects of imputed data on biodistance and classification. Results suggest that Hot-Deck imputation is the most accurate method with 25% missing data, with this imputation method consistently performing at the highest levels of agreement (up to ICC=0.97), with the least impact to the D^2 and, ultimately, classification. In severe instances of missing data (50%), IRMI consistently produced the highest levels of agreement. Kenyhercz and Passalacqua examined the effects of missing data using metric cranial data and found that when dealing with continuous variables, the kNN imputation method had the best performance in both moderate (25%) and severe (50%) missing data conditions.[3]

Non-Metric Data, Imputation, Missing Data

A89 Skeletal Sex Estimation in a Modern Cuban Sample

Meredith L. Tise, PhD, University of Lincoln, School of Life Sciences, Brayford Pool, Lincoln LN6 7TS, UNITED KINGDOM*

After attending this presentation, attendees will understand which skeletal elements and standard measurements of the cranium and postcranial skeleton are the most accurate when estimating the sex of modern Cuban individuals in a forensic anthropological context.

This presentation will impact the forensic science community by offering new techniques when analyzing skeletal remains that have the potential to be an individual from Cuba, most specifically when metrically estimating sex. This presentation will also incorporate the significance of this research with the recent political and economic changes between the United States and Cuba.

Craniometric and postcranial metric data were collected from 111 known modern Cuban individuals located at the Museo Antropológico Montane at the University of Havana in Havana, Cuba. This sample contains data from 65 male and 46 female individuals. Multivariate and univariate statistical analyses, including Discriminant Function Analyses (DFA), were conducted in SAS® 9.4 to establish classification functions and sectioning points with associated classification rates.

Out of the 27 standard cranial measurements collected with a MicroScribe® G2 digitizer, eight measurements were separated using a stepwise selection procedure to include GOL, XCB, ZYB, WFB, AUB, OBH, PAC, and MOW. Based on these eight cranial measurements, and the resulting classification function, females were correctly classified 86.05% of the time and males were correctly classified 87.50% of the time, based on the cross-validation classification rates.

Forty-one standard postcranial measurements were collected from the long bones of each individual, including the humerus, radius, ulna, femur, tibia, and fibula. The stepwise selection procedure selected 12 measurements that are the most accurate when estimating the sex of these long bones: HUMXLN, HUMEBR, RADXLN, RDH, RADAPD, RADTVD, ULNXLN, ORL, BCB, FEMEBR, TIBXLN, and TIBNFX. Based on the multivariate analyses, the humerus resulted in the highest overall cross-validation classification rate of 96.93%, followed by the radius with 92.17%. When assessing each stepwise selected measurement individually, the Humerus Epicondylar Breadth (HUMEBR) resulted in the highest cross-validation rate of 96.93%, followed by the ulna Olec-Radial Notch (ORL) with a classification rate of 90.97%. These results demonstrate a high accuracy for utilizing cranial and postcranial metric analyses with estimating the sex of the skeletal remains of Cuban individuals.

Not only will these skeletal sex estimation techniques be beneficial to forensic anthropologists in Cuba, forensic anthropologists practicing in the United States can also utilize the results of this research. According to the 2010 United States Census, the Cuban population increased by 44% in the United States from 2000 to 2010, with an increase from 1.2 to 1.8 million within those ten years.[1] In 2010, approximately 77% of Cuban individuals in the United States resided in the southeastern states, with the majority of these individuals living in Florida.[1] Therefore, forensic anthropologists conducting casework in Florida are most likely to be confronted with the need for methods derived from Cuban individuals.[2] Recent studies have demonstrated the difficulty and inaccuracy of using methods derived in the United States on Cuban individuals, primarily as a result of the differential population history Cuba has experienced since Spanish colonization took place in the late 1400s.[3,4] With the recent advent of diplomatic relations being restored between Cuba and the United States, collaborations between the two countries will begin to excel, including in the forensic science community.

A91 Cranial Morphological Sexing Trait Patterns Differ Across Populations

Monica M. Thompson, University of La Verne, 1950 Third Street, La Verne, CA 91750; Kaitlyn A. Lopez*, University of La Verne, 1950 Third Street, La Verne, CA 91750; and Kanya Godde, PhD*, 1950 Third Street, La Verne, CA 91750*

After attending this presentation, attendees will be aware of the similarities and differences in expression of four cranial morphological sexing traits between Egyptians and modern Americans. Further, attendees will understand the implications of these differences when applying the cranial morphological sexing technique, which could lead to an increase in the accuracy of estimating sex.

This presentation will impact the forensic science community by highlighting the limitations of the cranial morphological sexing method and showing how it can be applied successfully by knowing the morphological patterns specific to individual populations.

When applying the cranial morphological sexing technique, biological anthropologists adjust the method to suit the population under study. Population patterns in trait expression have not been formally published for testing and quantification in a forensic context. Thus, an evaluation of the different degrees to which cranial morphological traits are expressed across populations is necessary. The hypothesis this research tested was that traits of the cranial morphological sexing method differ in magnitude between modern Americans and Egyptians.

Two populations (N=457) were analyzed for each of the five major cranial morphological sexing traits: glabella, mastoid process, supraorbital margin, nuchal crest, and mental eminence. Modern Americans from two collections with documented sex, the William M. Bass Donated Skeletal Collection (Bass Collection) and Hamann-Todd, were observed on a scale of one through five for each of the five characteristics. The modern Americans represent inhabitants of rural and urban areas born during the past 186 years. The Egyptian sample is comprised of observations made on individuals from four sites, spanning Upper and Lower Egypt and from the Predyanstic through the New Kingdom time periods. The Egyptian collection is curated in the Phoebe A. Hearst Museum of Anthropology at the University of California, Berkeley (UCB).

As the Egyptian sample had few associated pelvises to verify sex, cranial measurements from the Giza Egyptian sample in the Howell's data set were input into discriminant analyses to create a discriminant function for an estimate of sex on the UCB Egyptian sample. The result was 97% accuracy of Howell's measurements against Howell's assigned sex. This population-specific discriminant function from Giza was then applied to the UCB Egyptian sample to estimate sex from cranial measurements. Only skulls with 80%-and-above accuracy rates from the discriminant function were retained.

A two-tailed Fisher's exact test with the Freeman and Halton adaptation for RxC tables was executed on the data categorized by sex (documented or established by the discriminant analysis described above), population, and degree of expression per trait. Mental eminence was not assessed as few mandibles were preserved in the Egyptian sample and expression of mental eminence was obscured by dental disease or edentulism in many of the modern Americans from the Bass Collection. Eight cross-tabulation tables were generated, while sex was controlled, to assess population and degree of expression. Of these eight analyses, only one was not significant at α=0.10 or higher (glabella in females), while the other results were all significant at the α=.01 level. Thus, in general, the null hypothesis can be rejected; the probability a particular sex will exhibit the same degrees of expression regardless of population affiliation is not supported. In this study, the degree of expression of these traits is population specific. It can also be concluded from the cross-tabulation tables that modern Americans tend to have a higher degree of expression of these traits than Egyptians.

The results demonstrate that these four traits cannot be universally applied for estimating sex from the cranium. Hence, forensic practitioners should be aware that population specificity ought to be factored into the application of this method. As regards the American and Egyptian populations, forensic anthropologists should anticipate that higher trait scores (e.g., five in males and three in females) are more frequent in modern Americans and that this is not solely attributable to sex.

This research was supported by a William M. Bass Endowment award and a University of La Verne Academy grant.

Modern Americans, Population Specific, Discriminant Analysis

A92 An Analysis of Sexual Dimorphism Using Geometric Morphometrics (GM) of the Femur and Tibia: The Use of GM in Assessing Sex of Fragmented Remains

Amanda K. Costello, MS, 511 Bienveneda Avenue, Pacific Palisades, CA 90272*

After attending this presentation, attendees will have a better understanding of the usability of GM to accurately assess sex of unidentified remains. Attendees will also be educated on which areas of two skeletal elements — the femur and tibia — preliminarily indicate they are more indicative of sex-dependent size and shape variation when compared to others.

This presentation will impact the forensic science community by providing a method for assessing sex of fragmented remains when other methods are not possible, which has the potential to provide the researcher with critical forensic information that may not otherwise be attainable.

Biological anthropologists have recently been utilizing GM to investigate sexual dimorphism among modern *Homo sapiens*. To analyze sexual dimorphism of the femur and tibia using GM, landmark data were registered using a MicroScribe® on 250 individuals of known sex and age at death from the William M. Bass Donated Skeletal Collection. The sample was limited to individuals of "White" ancestry in order to eliminate population bias. A combination of landmarks and semi-landmarks were collected on the proximal and distal epiphyses of each bone, which captured the overall size and shape variation present in the sample. Classification rates for males (ages 19 years to 96 years) and females (ages 29 years to 97 years) for the proximal femur were 80.8% and 78.4%, respectively; for the distal femur, 92.6% and 89.6%, respectively; for the proximal tibia, 80.8% and 83.2%, respectively; and for the distal tibia, 81.6% and 80.8%, respectively.

This study indicates the knee joint is the most dimorphic, followed by the ankle, then the hip. The results are similar to other studies that indicate the knee is more sexually dimorphic, though here it was found the distal femur was more dimorphic when compared to the proximal tibia. This preliminary research indicates that in comparison to standard measurements, GM may provide a more reliable method for sex estimation when used on the knee. Further research applications excluded landmarks to determine the usability of the method if fragmented remains are present due to taphonomic processes, such as the case may be in forensic circumstances. When landmarks were excluded simulating taphonomic damage, the distal femur still presented the highest classification rates, averaging more than 81% for males and females, followed by the distal tibia, averaging more than 73% for males and females, followed by the proximal tibia, averaging more than 71% for males and females, and the epiphysis with the lowest classification rate after landmark removal was the proximal femur, averaging more than 63% for males and females.

This application revealed which areas of the femur and tibia are more indicative of sex-dependent size and shape variation when this method was applied to a modern "White" population. These areas are controversial in that they are not areas previously associated with sexual dimorphism. Knowledge of these areas will change how future research analyzing sexual dimorphism of the skeletal elements of the leg is conducted.

Sexual Dimorphism, Geometric Morphometrics, Forensic Anthropology

A93 Metric Assessment of the Pubic Bone to Determine the Accuracy of Known and Novel Data Points for Sex Estimation

Kathleen A.S. Blake, PhD, State University of NY at Oswego, Dept of Anthropology, Mahar 441, Oswego, NY 13126; Hallie Gaffney*, State University of New York at Oswego, Mahar Hall, Anthroplogy Dept, Oswego, NY 13126; and Kristen Hartnett-McCann, PhD*, Office of the Chief Medical Examiner, Forensic Anthropology, 11 Shuttle Road, Farmington, CT 06032*

After attending this presentation, attendees will understand the variation of 13 metric and 3 non-metric traits on the pubic bone from an adult skeletal sample with known demographic data.

This presentation will impact the forensic science community by: (1) evaluating pubic bone dimorphism between adult males and females from metric and non-metric traits; (2) providing landmarks and measurements that demonstrate reduced error and increased reliability of sex assessment of the pubic bone to allow for comparison by future researchers; and, (3) assessing novel data points that suggest additional sex determination methodologies than previously used. This presentation adds to the research on reliability and repeatability of forensic anthropological sex determination methods through other analysis of adult skeletal samples with known age and sex compared to previously published rates. Additionally, this research quantifies shape differences in the pubic bone of males and females, adding to the growing list of studies undertaken to meet the rigorous *Daubert* ruling scientific standards.[1]

The determination of the biological sex of skeletal remains is an important early step in forensic and archaeological analyses. Not only does it eliminate roughly half of the population from the search in forensic cases, but components of a biological profile, such as stature, ancestry, and age at death, are based on that initial sex assessment.[2] While distinctions exist between male and female skeletons before birth, the more visible skeletal dissimilarities manifest at puberty, when hormones stimulate secondary sex characteristic development.[3] Anthropologists use the pelvis as it is the most sexually dimorphic element of the human skeleton, both morphologically and metrically, due to functional requirements of both bipedality and safe parturition in females.[4,5] Phenice first recognized that the ventral arc, subpubic concavity, and medial border of the inferior pubic ramus were all highly sexually dimorphic.[6] Moreover, the pubic bone shape can be used to visually assess sex; in females, the body of the pubis is larger and more rectangular, while male pubic bones are somewhat triangular in shape.[7]

This study examines a modern, diverse sample from the Maricopa County Forensic Science Center (FSC) in Phoenix, AZ. A subset of the FSC collection, n=400, (120 females and 280 males) was examined by three observers. All measurements were taken from the left side when available; if damaged or missing, the right side was substituted. A total of 13 measurements from both previously identified and novel points were taken and included height and breadth of face, several measurements of the pubic body from the obturator foramen, and ischiopubic ramus thickness. In addition, three non-metric features were visually evaluated: the ventral arc, the subpubic concavity, and the overall shape of the pubic body.

This research determined that a relationship exists between 12 measurements and biological sex. Between males and females, no significant differences were found in the variances for the measurements taken, with nearly all normally distributed. Independent t-tests showed significant differences in the means for 12 of the 13 measurements, with most at the p=.000 level. All but one measurement showed correlations to sex at either a significance level of 0.01 or 0.05, with pubic body width and perpendicular inferior pubic body width the strongest at .550 and .531, respectively. Non-metric traits also correlated to sex; for example, the ventral arc correlated to sex at the 0.01 significance level with a correlation coefficient of 0.792. Inter-observer reliability was tested using intra-class correlation. For the two most significantly correlated traits, pubic body width and perpendicular inferior pubic body width, both supported the reliability of these measures, with the pubic body width intra-class correlation the highest at 0.962, with a 95% Confidence Interval (CI) (0.954, 0.969).

In forensic anthropology today, sex determination methods must meet forensic legal standards of reliability and repeatability and be developed from samples of known age and sex; however, current methods provide limited accuracy, as many methods are subjective, non-metric, and developed on non-modern skeletal populations.[8] The creation of standardized, repeatable, metric sex determination methods from modern populations is essential. Considerable variation was present in the shape and size of pubic bones in this population skeletal sample and landmark determination was more difficult for some measurements than others; however, once identified, these measurements were reliable and they show promise as metric determinants of sex on the pubis.

Sex Determination, Pubic Bone, Metric Assessment

A94 An Assessment of Sexual Dimorphism in the Sternal Fourth Rib: A 2D Morphometric Approach

Andrew C. Seidel, MA, Arizona State University, Human Evolution/Social Change, PO Box 872402, Tempe, AZ 85287-2402; and Laura C. Fulginiti, PhD, Forensic Science Center, 701 W Jefferson, Phoenix, AZ 85007*

After attending this presentation, attendees will be informed about the presence of measurable sexual dimorphism in the contours of the superior and inferior margins of the sternal two centimeters of the fourth rib.

This presentation will impact the forensic science community by providing data suggesting that the shape of the sternal end of the fourth rib has the potential to be used in the estimation of sex from isolated ribs. In turn, this finding would allow for the construction of biological profiles for unknown decedents for whom more traditional skeletal indicators of sex (e.g., cranium and os pubis) are damaged or unavailable.

This research was conducted using the Hartnett-Fulginiti collection housed at the Forensic Science Center in Maricopa County, AZ. This collection is comprised of more than 600 specimens of pubic symphyses and associated sternal ends of the fourth ribs from decedents of known sex, age at death, and ancestry. Two hundred individuals (100 males, 100 females) were randomly selected from the collection for analysis. Specimens were positioned so they were level and photographed with a scale. Where possible, left fourth ribs were utilized. When left rib ends were damaged or otherwise unavailable, right rib ends were photographed and the resulting digital image was mirrored in order to match the orientation of the left rib images. Specimens that were damaged or less than 2.5cm in length were removed from the analysis, resulting in a final sample size of 140 individuals (70 males and 70 females) ranging from 18 years to 93 years of age.

Each image in the final sample size was calibrated using the photographed scale and a suite of 40 landmarks were digitized at approximately 1.0mm intervals beginning at the edge of the sternal pit and extending for a length of 2.0cm along the contours of both the superior and inferior margins of the rib. Actual interval markings ranged between 0.97mm and 1.03mm due to software and image resolution limitations. Landmark data were then subjected to a Generalized Procrustes Analysis (GPA) to investigate differences in shape between male and female sternal rib contours. As GPA removes the effects of size, location, and rotation within landmark configurations, it should negate the effects of body-size dimorphism and allow for the direct comparison of sternal rib shape between males and females. The resulting Procrustes coordinates were then subjected to a principal components analysis and component scores were evaluated for evidence of sexual dimorphism.

Results indicate that there are significant differences between males and females in regard to their first Principal Component (PC1) scores (t=11.326, v=138, p-value <2.2e-16). In this analysis, PC1 accounts for 57.8% of the total variation in shape and represents (in females) a constriction of the rib shaft near the sternal end as well as an overall more elongate shape to the sternal 2cm of the fourth rib. In contrast, males typically lack such a sternal constriction and exhibit a broader sternal rib morphology, resulting in a slightly flared appearance. These differences are confirmed by a Discriminant Function Analysis (DFA), the results of which indicate a Procrustes distance between male and female landmark configurations of 0.093 and a Mahalanobis distance of 4.045, both of which are significant (p-value <0.0001 as determined by permutation tests using 1,000 iterations). Moreover, the results of a leave-one-out cross-validation of the DFA resulted in a 21.4% misclassification rate for females and a 22.8% misclassification rate for males. Decreasing the number of utilized landmarks to 30 increased the percentage of total shape variation accounted for by PC1 to 58.9% and resulted in improved misclassification rates produced by cross-validation (17.1% for females and 20.0% for males).

These results suggest that meaningful sexual dimorphism exists in the shape of the sternal fourth rib and that it may be profitably employed in the estimation of sex for unknown decedents, especially in situations in which more commonly used techniques cannot be employed.

Fourth Rib, Sex-Estimation, Morphometrics

A95 A Geometric Morphometric Comparison of Pelvic and Cranial Sexual Dimorphism

Kaleigh C. Best, MS, 2800 W Murphysboro Road, Carbondale, IL 62901; Luis L. Cabo, MS, Mercyhurst University, Dept of Applied Forensic Sciences, 501 E 38th Street, Erie, PA 16546; and Heather M. Garvin, PhD, Mercyhurst University, Dept of Applied Forensic Sciences, 501 E 38th Street, Erie, PA 16546*

After attending this presentation, attendees will understand how sexual size and shape dimorphism compares in the human os coxae and cranium, including which shape changes contribute the most to sex differences.

This presentation will impact the forensic science community by providing cross-validated correct sex classification rates for the os coxae and cranium and demonstrating to forensic anthropologists which of the two elements provides the most reliable sex estimation when case results may be contradictory.

In humans, the os coxae and the cranium are commonly referred to as the most sexually dimorphic regions of the skeleton and thus are often used to estimate the sex of individuals in a variety of physical anthropology subfields, including paleoanthropology, bioarchaeology, and forensic anthropology. Although there are numerous studies analyzing either pelvic or cranial sexual dimorphism, these studies utilize various populations, samples, sample sizes, types of data, methods, or statistical analyses, making a direct comparison between the resultant dimorphism values invalid. Only one study was found in which pelvic and cranial dimorphism was analyzed using a single sample, but it only compared non-metric sex estimation results, which are known to be somewhat subjective. The goal of this study was to use landmark data and geometric morphometric analyses to compare sexual size and shape dimorphism in the os coxae and cranium in a single sample. The use of a single study sample for both analyses means that the obtained sex classification results are directly comparable and will provide forensic anthropologists with information regarding the reliability of these two elements in sex estimation methods.

Forty-two landmarks from the cranium and 12 landmarks from the os coxae were digitized using a MicroScribe® on a sample of 113 United States Black adults (aged 17 years to 70 years) from the Hamann-Todd Osteological Collection. Following a Procrustes superimposition, principle component and discriminant function analyses were used to assess and compare the degree of sexual shape and form (combined shape and size) dimorphism present in both skeletal regions. Univariate analyses were performed to evaluate which specific shape changes were contributing the most to the sex differences. Centroid size was used to assess sexual size dimorphism.

The results of the shape, form, and size analyses all indicate that the os coxae is more sexually dimorphic than the cranium. The discriminant function analysis performed on the os coxae shape variables resulted in a cross-validated correct sex classification rate of 99.1%, compared to 84.1% in the cranium. Including size in the shape analyses (i.e., form) and analyzing size independently (i.e., centroid size) did not increase sex classification rates, indicating that sex differences in these elements occurs primarily in shape. The geometric morphometric analyses confirmed that relative pubis length, sciatic notch breadth, and subpubic concavity were the most important shape variables in pelvic dimorphism. In addition, os coxae height relative to ilium breadth also contributed to sex differences. In the cranium, the geometric morphometric analyses revealed sex differences in facial height, vault breadth, cranial base flexion, nasal width, and glabellar prominence.

As this study uses a single sample to analyze sexual dimorphism in the os coxae and cranium, it eliminates many extraneous variables (e.g., sample and method differences) and allows a direct comparison between the skeletal regions. Results confirm that the os coxae is significantly more dimorphic than the cranium; thus, when assigning sex to an unknown skeleton, forensic anthropologists should rely more heavily on pelvic morphology. Geometric morphometric shape analyses conducted on the os coxae landmark data can discriminate between the sexes with up to 99% accuracy and provide an objective method to quantitatively analyze traditional non-metric sex traits.

Sex Estimation, Os Coxae, Cranium

A96 A Reassessment of Walker Cranial Non-Metric Traits on Undocumented Border Crossers Along the South Texas Border

Brittany S. McClain, BA, Texas State University, 8901 Jesse James Drive, Austin, TX 78748; Cassie E. Skipper, BS, Texas State University, New Braunfels, TX 78130; and Marilyn Isaacks, BA, Texas State University, 15931 Watering Point Drive, San Antonio, TX 78247*

After attending this presentation, attendees will know to proceed with caution when sexing Hispanic crania using Walker visually assessed cranial traits as Hispanic populations do not exhibit the full range of cranial morphological variation assumed in this method.

This presentation will impact the forensic science community by aiding in this humanitarian effort to identify and repatriate these individuals by acknowledging the necessity for population-specific techniques and to make other researchers aware of the potential issues when solely using crania for sex estimation.

The increase in undocumented border crosser deaths in the harsh environments along the South Texas border has created a present humanitarian disaster in which forensic anthropologists must utilize all available skeletal resources, even when little remain. The problem is especially acute in Brooks County, TX, where remote ranchland is abundant, thereby making it easier for migrants to cross the Texas-Mexico border, although it is also more perilous due to weather conditions. Project Operation Identification (OpID) was created at Texas State University in response to the increasing border crosser fatalities. OpID addresses this humanitarian disaster and serves to identify and repatriate the skeletal remains of undocumented border crossers who died crossing the South Texas border.

The unforgiving Texas environment can both limit the recovery of skeletal elements and lead to poor preservation. As a result, OpID utilizes all available skeletal material to create a biological profile. When pelvic skeletal elements are not present to estimate sex, the cranium is used as an alternative and analyzed using the Walker non-metric sexing method, which is based on scoring visually assessed cranial traits.[1] This method has traditionally been used on all populations without dispute when no other appropriate technique is available for the specific population.

It is currently unknown whether Hispanic populations exhibit the full range of cranial morphological variation assumed in the Walker scoring system. The current research serves to test the applicability of the Walker cranial non-metric sexing method to a Hispanic sample and to discern if these individuals express the expected full range of variation. Inter-observer reliability between the three researchers was assessed and confirmed prior to scoring the crania. The OpID crania were seriated based on each of the five traits and scored separately. Twenty-one crania were scored for nuchal crest, mastoid process, supra-orbital margin, and glabella. Because one individual was missing a mandible, only 20 crania were scored for mental eminence.

The results for each trait were analyzed using a logistic regression equation provided by Mercyhurst University to estimate sex, Chi-square goodness of fit, and Cramer's V (0.584, *p*-value=.02).[2] The Chi-square results of this preliminary study show the estimated sex of the OpID individuals based on pelvic morphology is significantly different from the sex estimated using the Walker cranial non-metric method (X2=7.853, df=2, *p*-value=.02); however, there was a strong correlation between sex and the traits scored (Cramer's V=0.584, *p*-value=0.02). Further, the Hispanic sample tested did not exhibit the full range of variation for nuchal crest, supra-orbital margin, and mental eminence described in the Walker article. While the Walker method can be used to estimate sex when only crania are present, researchers should express caution when using this method until the scores are shifted to more accurately represent the Hispanic population.

In conclusion, the sampled Hispanic crania do not exhibit the full range of variation outlined in Walker.[1] To sex the crania of Hispanic individuals, a more appropriate method should be employed and utilized to account for the range of variation exhibited by Hispanic crania. The impact of the present research will aid in this humanitarian effort to identify and repatriate these individuals by acknowledging the necessity for population-specific techniques and to make other researchers aware of the potential issues when solely using crania for sex estimation.

Undocumented Border Crossers, Sex Estimation, Cranial Non-Metric Traits

A97 Stable Isotope Investigation of Mother-Infant Pairs and the Implication for Forensic Casework

Inga Siebke, Sulgenauweg 40, Bern, SWITZERLAND; Fabian Kanz, PhD, Medical University of Vienna, Department of Forensic Medicine, Sensengasse 2, Vienna, YT 1090; Carsten Witzel, PhD, University of Hildesheim, Marienburger Platz 22, Hildesheim 31141, GERMANY; and Sandra Lösch, PhD, University of Bern, Institute of Forensic Medicine, Dept of Physical Anthropology, Sulgenauweg 40, Bern 3007, SWITZERLAND*

After attending this presentation, attendees will gain: (1) an understanding of the significance of stable isotope analysis and tooth histology in evaluating the survival time of disposed neonates; and, (2) knowledge of the applicability of bioarchaeological research for forensic science.

This presentation will impact the forensic science community by providing results using an innovative approach of stable isotope analysis combined with tooth histology in the context of stillbirth or infanticide. The research will add information to the knowledge of neonatal stable isotope values.

The news frequently reports on forensic investigations in relation to disposed dead infants. The greater the decomposition, the more difficult it becomes to evaluate the cause of death. The main question often raised is whether the neonate was stillborn or was a victim of infanticide. An indication of whether a neonate was born alive is the presence of a Neonatal Line (NNL); however, current research has shown that the NNL is detectable after seven to ten days of survival.[1,2] Stable isotope analysis is frequently used in forensic and archaeological settings and the relationship of the values between mother and infant has been studied.[3-6] In contrast, the question of detecting stillbirth or infanticide has received less attention.

It has been shown that breastfed children exhibit increased δ15N values based on stable isotopes of the hair and fingernails.[3,4] This is not applicable when decomposition is too advanced. Therefore, the goal was to investigate the collagen values of δ15N of mother-infant pairs as neonatal bones are often recovered at forensic scenes.

Three mother-infant pairs with reliable relations from St. Poelten, Austria, were used to evaluate the hypothesis that breastfed neonates express higher δ15N values than their mothers. For the stable isotope analysis, samples of the same skeletal element were taken. Tooth histology was performed if teeth were available. Additionally, 17 human remains from the archaeological site of Petinesca, Switzerland, were analyzed.

The collagen extraction was performed following a modified acid-base extraction method.[7] Isotope ratio mass spectrometry was used for the calculation of the 15N/14N ratio and collagen quality was evaluated. For the tooth histology, a standard protocol was followed, a light microscope and a scanning electron microscope were employed, and micro radiography was performed.[2]

The stabile isotope results of the mother-infant (estimated age: six to ten lunar months) pairs indicate that no breastfeeding signal is present and no NNL was observed. For the second series (estimated age: 8.5 lunar months to 2 months *ex utero*), a breastfeeding signal was observed for all except one individual that exhibited decreased δ15N values compared to the other infants and similar δ15N values to the female average. The tooth histology of this individual revealed no NNL.

It is seen that stable isotope analysis can assist in the evaluation of the survival time of neonates; however, limitations such as the unknown turnover rate of collagen in developing bones require controlled studies. In conclusion, it is believed that stable isotope analysis could become a useful tool for forensic science when dealing with neonatal remains.

Stable d15N Isotope, Neonatal, Survival Time

A98 Bone Histology Sampling Sites for the Identification of Undocumented Border Crossers Along the United States-Mexico Border

Lauren Alyssa Meckel, BS, Texas State University, 1509 Marlton Street, San Marcos, TX 78666; Sophia Mavroudas, MA, Texas State University, 601 University Drive, ELA 232, San Marcos, TX 78666; Victoria M. Dominguez, MA, Ohio State University, Division of Anatomy, 1645 Neil Avenue, Columbus, OH 43210; and Kate Spradley, PhD, Texas State University, Dept of Anthropology, 601 University Drive, San Marcos, TX 78666*

After attending this presentation, attendees will understand the difficulties of estimating age at death of Undocumented Border Crossers (UBCs) along the United States-Mexico border, and the importance of sampling site choice for histological age estimation.

This presentation will impact the forensic science community by resolving certain issues challenging anthropologists working to identify UBCs in the growing humanitarian crisis along the United States-Mexico border.

The death of UBCs along the United States-Mexico border is an unacknowledged humanitarian crisis currently affecting the United States. The immense skeletal diversity represented within this group presents new challenges in identification as population-specific methods are lacking for this group. Since 2013, the Forensic Anthropology Center at Texas State (FACTS) has been working to identify UBCs from Brooks and surrounding counties in Texas. As part of this effort, FACTS has accepted 78 UBCs from exhumations and from the Webb County, TX, Medical Examiner's Office. Due to the nature of the UBC deaths along the border, anthropologists play a vital role in identifying these individuals and repatriating their remains to grieving families

A critical aspect of UBC identification is an accurate age-at-death estimate to narrow the list of potential matches for repatriation. Previous studies have confirmed that combining both gross morphology and histomorphology age estimation provides a more complete picture of age-related skeletal changes. The goal of this study is to examine which bone histology sampling site is the most appropriate indicator of UBC age at death to help increase identifications and gain a better understanding of skeletal age in UBCs.

The remains of N=29 (15 males and 14 females) UBCs were examined using histological analysis of the femur and of the midshaft of the sixth rib.[1-3] The sex of each individual was determined either by soft tissue or skeletal analysis. Due to sampling constraints, only the anterior femur at the midshaft was sampled and analyzed. Gross morphology estimates were gathered from case reports and age indicators included pubic symphysis, sternal rib ends, and auricular surface.

To determine the most appropriate histological sampling site for UBC identification, the mean age for each site-specific histological method was calculated. Additionally, the femoral and rib age estimates were compared to the gross morphology age range estimates from each individual. Agreement between histology age and gross morphology age was determined by whether the histology point age estimates fell within the gross morphology age estimate ranges. Inter-observer error for each histological method was calculated.

The mean ages for the femur and rib methods were 45.7 years and 37.1 years, respectively. Results show that 2% of the femoral histology point age estimates overlap with the gross morphology age estimates, while 93% of the rib histology point age estimates overlap with the gross morphology age estimates. Inter-observer error was non-significant at $p<0.05$. Compared to the gross morphology mean age (33.7 years), both of the histology methods overaged the sample, but the rib method had a lower inaccuracy. This suggests that with current available methods, the rib is a better sampling site for UBC identification. Overall, the femur method was a poor indicator of UBC skeletal age; however, the remodeling counts of the femur show a positive trend with age (R^2=0.51). This suggests that although this method is not applicable to UBC age-at-death estimation, there is potential for developing new methods using the anterior femur to accurately estimate UBC age at death.

The results of this study indicate that the midshaft of the sixth rib is the most appropriate histological sampling site for UBC identification. The results also suggest that future research focusing on the anterior femur of UBC groups could prove appropriate for UBC identification if new methods are developed with appropriate demographics.

Histology, Aging, Operation Identification

A99 Estimation of Age-at-Death Using Femoral Cortical Thickness, Biomechanical, and Histological Variables

Megan E. Ingvoldstad, PhD, DPAA Laboratory, 310 Worchester Avenue, Bldg 45, Joint Base Pearl Harbor-Hickam, HI 96853; and Christine M. Pink, PhD, Joint POW/MIA Accounting Command, 310 Worchester Avenue, Bldg 45, Joint Base Pearl Harbor-Hickam, HI 96853-5530*

After attending this presentation, attendees will see that standardized locations of the adult human femoral midshaft lose cortical thickness differentially with increasing age. Discovery of a uniform pattern of bone loss among this variability may allow for production of age-at-death estimates from unidentified skeletal remains.

This presentation will impact the forensic science community by eliminating a method proposed to utilize multiple types of femoral midshaft cross-sectional data to produce age-at-death estimates from unidentified adult human skeletal remains.

Literature review indicates that once the femur is fully developed, biomechanically adapted, and periosteally adjusted, a net loss of cortical bone begins as the amount of bone deposited on the periosteal surface lessens in comparison to the amount of bone removed from the endosteal surface. Decreasing bone gain on one surface and increasing loss from another changes the size, shape, and strength of the femur throughout adulthood.

To determine whether differential cortical bone loss occurs that can be exploited for production of age-at-death estimates, cortical thickness data was collected from 16 standardized locations (0º (anterior), 22.5º, 45º, 67.5º, 90º (medial), 112.5º, 135º, 157.5º, 180º (posterior), 202.5º, 225º, 247.5º, 270º (lateral), 292.5º, 315º, and 337.5º) around each of 200 adult femoral midshaft cross-sections originally harvested by M.F. Ericksen from George Washington University (GWU) dissecting room cadavers. The sample was composed of 97 males and 103 females largely of European descent, ranging in age from 30 years to 97 years (mean=71 years, standard deviation=12 years).

Results indicate median cortical thickness differs significantly around the femoral midshaft ($X2(15)=609.567$, $p<0.0005$). Specifically, post-hoc pairwise comparisons discovered 71 statistically significant differences between median cortical thicknesses ($p\leq0.05$). From these results, a general pattern emerges where the smallest median cortical thicknesses occur in the anteromedial and posterolateral quadrants of the femoral midshaft, while the anterolateral quadrant possesses all of the largest cortical thicknesses, with the one exception of the posterior 180º location — the linea aspera. Additionally, Pearson and Spearman's rank order correlations found moderately negative statistically significant correlations between age and all cortical thickness locations, with the highest grouped among the anterior, anteromedial, posterior, and posterolateral femoral cortices, and lowest among the medial and lateral femoral cortices. This finding, combined with locally weighted scatterplot smoothing curves of the data, suggests cortical thickness is not lost uniformly with age; rather, the anterior and posterior cortices lose more thickness beginning earlier than the medial and lateral cortices.

An age-predicting linear regression equation utilizing all cortical thickness location data revealed Standard Error of Estimate (SEE) and adjusted R2 values (±10.82 and 0.1957, respectively) comparable to those produced using standard histological methods. Unexpectedly, equations composed from only anterior and posterior cortex data did not perform superiorly. Rather, the best performing equation, Age=89.18+(1.99×135º)+(-2.08×157.5º)+(-3.66×225º), revealed similar SEE and adjusted R2 values (±10.58 and 0.2314, respectively). This equation was tested on an independent sample of 22 femoral midshaft cortices obtained from The Ohio State University Department of Anatomy. Comparison of known ages at death to point age estimates revealed inaccuracies as high as 40 years.

Given these results, previously collected biomechanical and histological data were additionally included to determine what combination of cortical thickness, biomechanical, and histological variables was associated with the lowest SEE and highest adjusted R2 value. The best performing equation, Age=96.10+(-7.49×Ix/Iy)+(-3.67×225º), again produced a high SEE and poor adjusted R2 value (±10.58 and 0.2307, respectively).

Overall, these findings reinforce how femoral midshaft variables primarily reflect mechanical environment regardless of age and suggest there is too much variation in mobility among modern humans for femoral shape, thickness, or remodeling data to be useful indicators of age at death, in any combination.

Age-at-Death, Cortical Thickness, Multiple Linear Regression

A100 Transformation of the Department of Defense's (DoD's) Central Identification Laboratory (CIL): A Historical Review of Its Scientific Personnel and Primary Architects as It Embraces the Tides of Change

MariaTeresa A. Tersigni-Tarrant, PhD, Saint Louis University School of Medicine, Center for Anatomical Science, 1402 S Grand Boulevard, M306, St. Louis, MO 63104; and Denise To, PhD, JPAC-CIL, 310 Worchester Avenue, Bldg 45, Joint Base Pearl Harbor-Hickam, HI 96853*

After attending this presentation, attendees will be provided with a pertinent example of the Academy's 2016 Meeting theme of "Transformation: Embracing Change." The DoD parent organization of the CIL has again reorganized to streamline efforts in its noble mission. After this presentation, attendees will better understand the history of the CIL, its primary architects, and scientific personnel.

This presentation will impact the forensic science community by illustrating how the history of the CIL, with respect to its practitioners and research, has influenced forensic science. This historical review of the CIL may encourage attendees to pay greater attention to changes made by the DoD as to how it chooses to integrate forensic anthropologists to contribute to identification, since this precedent may influence how forensic anthropology is applied in other medicolegal settings worldwide.

The mission of the DoD's Defense POW/MIA Accounting Agency (DPAA) is to search, recover, and identify service personnel still missing from past United States conflicts. The DPAA represents the January 2015 merger of three federal organizations (the Joint POW/MIA Accounting Command (JPAC), Defense POW/Missing Personnel Office, and Life Sciences Equipment Laboratory). The DPAA's Laboratory is the scientific nucleus of the mission, as its anthropologists regularly direct archaeological recovery operations, analyze skeletal material accessioned from these global recoveries and disinterments, and conduct analyses on incident artifacts, all for the goal of positive forensic identification and casualty resolution of our missing service personnel.

The recent merger and transformation of the DoD's accounting effort is nothing new to the Laboratory, as its history includes various transitions and names, although the terms Central Identification Laboratory have been at its core since 1948. This history includes the CIL at Schoffield Barracks in Hawaii, the Central Identification Unit in Japan, laboratory presence in various mortuaries in the Philippines and Vietnam, the CIL-Thai in Thailand, the CILHI in Hawaii, and the JPAC-CIL (at Joint Base, Pearl Harbor-Hickam, Hawaii and Offutt Air Force Base, Nebraska). Most recently, the CIL has become the DPAA-Laboratory. As such, the transformational history of the CIL's participation in the DoD's efforts to identify missing service personnel reflects the history of forensic anthropology itself. The CIL's chief architects and influential scientific staff include Mildred Trotter, T. Dale Stewart, Ellis Kerley, Thomas McKern, and Thomas Holland (among many others). Hundreds of forensic anthropologists (including many Diplomates of the American Board of Forensic Anthropology (ABFA), forensic odontologists, and forensic archaeologists have worked at the CIL. The subsequent global influence of the CIL throughout forensic science is unquestionable.

The CIL has never been autonomous, as it has functioned under the roof of federal organizations, including the United States Army and Navy; however, the CIL's primary obligations have always been to science itself, by practicing and maintaining excellence in the field. While sometimes incongruent priorities and laypeople's good intentions pull the Laboratory in disparate ways, the CIL's commitment to the best practices of forensic anthropology and forensic archaeology is unwavering. Its international accreditation in crime scene processing, forensic biology, and trace evidence analysis has paved the way for other laboratories to do the same. The CIL was integral in responding to the National Defense Authorization Act (NDAA) 2010 National Academy of Sciences' call for improvements in forensic science by co-founding, with the Federal Bureau of Investigation (FBI), the Scientific Working Group in Anthropology (that formulates best practices for forensic anthropologists), which subsequently transformed into the National Institute of Standards and Technology's Department of Justice Organization of Scientific Committees Anthropology Subcommittee. Additionally, its regular activities in many foreign countries have helped shape the global growth of forensic science.

For the DPAA Laboratory to embrace this most recent parental change to its structure, it is therapeutic to acknowledge the historical legacy of its predecessor organizations, as well as acknowledge the contributions that former CIL scientists have made to many subfields in the forensic sciences. This presentation provides a visual representation of the past, so that we may be better prepared to embrace the future. Additionally, given the heavy involvement of federal lawmakers in the transition of the CIL to the DPAA Laboratory and the scrutiny on the forensic sciences in the United States, it is important that practitioners are aware of this transition process and how its ramifications can affect the discipline.

Forensic Anthropology, CIL, Department of Defense

A101 Thirty Years of the Forensic Data Bank and Data Collection Procedures (DCP) 2.0: Continuity and Transformation

Stephen D. Ousley, PhD, Dept of Anthropology/Archaeology, Mercyhurst University, 501 E 38th Street, Erie, PA 16546; Richard Jantz, PhD, University of Tennessee, Dept of Anthropology, Knoxville, TN 37996-0720; Natalie R. Langley, PhD, Lincoln Memorial University, DeBusk College Osteopathic Med, 6965 Cumberland Gap Parkway, Harrogate, TN 37752; Kate Spradley, PhD, Texas State University, Dept of Anthropology, 601 University Drive, San Marcos, TX 78666; and Beatrix Dudzik, PhD, 250 S Stadium Hall, Knoxville, TN 37996*

After attending this presentation, attendees will learn some results of 30 years of data collection and new directions with the Forensic Data Bank (FDB), an important resource for forensic anthropology.

This presentation will impact the forensic science community by highlighting the ongoing growth and evolution of the FDB, assuring its continued relevance to forensic anthropologists.

The FDB was established through a grant from the National Institute of Justice (NIJ) in 1985 to meet the recognized need for updated osteological data. Modern forensic cases could not be analyzed adequately based on data from 19th-century anatomical collections.[1] For 30 years, the FDB has been a source for much of the research in forensic anthropology.[2] Numerous researchers have requested and used data from the FDB. The main goal of the FDB — to update data for estimates of sex and ancestry — has been accomplished, but data collection, like human variation, is an ongoing process. The data have been used to more fully appreciate the secular changes in American groups that have occurred over the past 200 years. Also, reflecting demographic trends, the data have expanded to include a substantial number of Hispanics, the largest ethnic group in the United States, which includes individuals from at least six countries from North, Central, and South America.[3]

Contributions from other forensic anthropologists, which were to sustain the FDB, have waxed and waned, but thanks to the efforts of Richard Jantz, data collection through the University of Tennessee (UT) students has been ongoing and includes new and expanded data sets. For example, when the FDB began, 3D digitizers were unknown in anthropology. Digitizers record 3D landmark coordinates, which can be analyzed using Geometric Morphometric (GM) methods. Additionally, Interlandmark Distances (ILDs) can be calculated from the landmark coordinates. Both GM analyses and ILDs have proven valuable in the statistical classification of human remains. Digitizers have figured prominently in FDB data collection, with nearly all craniometric data collected in the past 15 years using a digitizer. In recent years, more cranial and postcranial data have been collected from Mexico, Guatemala, Germany, South Africa, Japan, Korea, China, and Thailand.

Thanks to the collection of traditional craniometric and postcranial measurements, new methods were developed for statistical classification methods using FORDISC® or other programs and have made it easier to understand morphological variation and sexual dimorphism in American groups.[4] Stature estimation has been greatly simplified, refined, and standardized thanks to FDB data and FORDISC®. The new methods of estimating ancestry, sex, and stature demonstrate the synergistic connection between data and practical applications to help answer forensic questions. The ongoing FDB data collected will reflect upcoming measurement changes and improvements known as DCP 2.0.

One unexpected result was that age indicators, such as Todd and Suchey phases, have not been as informative as hoped. The scores show much higher correlations to known age than any published blind studies, meaning that most observers scored the indicators after a positive identification and knowing the age of the decedent. Hopefully, recording of other age-informative traits, such as traits that can be used in transition analysis, scored before positive identification, will be more valuable in the future.

More recently, other data, such as dental morphology observations, which have been shown to be useful in ancestry estimation, have been added to the FDB.[5] The new kinds of data in the FDB will be incorporated into new statistical software for sex and ancestry estimation and will necessitate new statistical methods to analyze them, such as logistic regression, Bayesian classification, kernel probability density classification, and k-Nearest Neighbor classification.[6] Additionally, the new software will incorporate machine learning classification methods. Additional features such as outlier detection and data transformations will make the software useful for exploratory data analysis and general research, and routines for handling missing data will help make the most of the reference samples.

The data banking concept was recently extended to subadults through the Pediatric Radiology Interactive Atlas (Patricia), which contains more than 45,000 radiographs from individuals up to 20 years old; other researchers have been compiling measurements, radiographs, and Computed Tomography (CT) and Magnetic Resonance Imaging (MRI) scans, and making them available online.[7] Data and methods from publications, Patricia, and other online sources could also be incorporated into the FDB and software. Age estimation for adults and subadults using transition analysis and other methods will also be part of the software package, which will make it much easier to record wide-ranging standardized osteological observations and submit information to the FDB.

A102 Multidisciplinary Approach of Forensic Science in Historical Study: St. Fortunato of Serracapriola (Italy)

Francesco Sessa, MS, Ospedale Colonnello D'avanzo, Viale Degli Aviatori 1, Foggia 71100, ITALY; Gabriela Perilli, MD, Viale degli Aviatori 1, Ospedale Colonnello D'Avanzo, Foggia 71100, ITALY; Christian Zammit, MD, University of Malta, Dept of Anatomy, Faculty of M, Msida, MALTA; Santina Cantatore, Viale degli Aviatori 1, Foggia 71100, ITALY; Fabrice F. Dedouit, 1 Avenue Du Professeur Jean Poulhes, Toulouse Cedex 9, FRANCE; Giuseppe Guglielmi, PhD, Viale Pinto, Foggia 71100, ITALY; and Cristoforo Pomara, MD, PhD, University of Foggia, Dept Forensic Path, University of Malta, Dept of Anatomy, Faculty of Med & Surg Biomedical Sci, Foggia, Misida, Malta 71100, ITALY*

After attending this presentation, attendees will appreciate St. Fortunato of Serracapriola (Italy) as a historical figure and the role that forensic science can play in bringing scientific evidence to support historical findings.

This presentation will impact the forensic science community by presenting a multidisciplinary approach in forensic science to the remains of a historical figure venerated as a Saint by the Catholic Church.

This presentation discusses the case of St. Fortunato, who lived in Rome in the 3rd century AD. Although there are no historical references about St. Fortunato's martyrdom, his death dates back to the persecution of Christians under Maximinus Thrax, the Roman Emperor from 235 AD. In 1761, St. Fortunato was hailed patron *minus principalis* of Serracapriola, a small town in the area of Foggia (Puglia region), and in 2010 (250 years later), his remains were exhumed by mandate of the clergy for a complete forensic analysis. It is rare that such a forensic multidisciplinary approach is applied to the study of ancient sacred human skeletal remains, as finding data not consistent with St. Fortunato's life might bring into question the believers' faith.

After exhumation, all bones were cleaned and classified according to anatomical topography. A detailed description of bone status was performed and osteological measurements were taken. Multi-Slice Computed Tomography (MSCT) was performed. The elements were placed on the scan table anatomically for easier radiological interpretation; scans were filtered for specific elements in order to determine sex, age, stature, and any pathologies. The radiological data were consistent with a young male, 153cm to 165cm tall, with no signs of pathological or traumatic conditions. Permission was granted for a piece of bone (7g of femur) to be radiocarbon dated. The resulting date indicated an age of approximately 230 AD (95.4%), which is compatible with St. Fortunato's death.

A complete genetic analysis was performed in order to genotype the bony samples. Forensic methodologies were therefore applied in this study, because ancient DNA is often problematic to study given its inherent nature. In ancient skeletal remains, the quantitative and qualitative differences in results can be attributed to environmental factors or to storage conditions. In addition, when dealing with religious relics, one is often limited to investigating a small sample.

Previous protocols were slightly amended in order to improve the DNA quality and minimize the need for the use of expensive equipment and chemicals, yet still ensure a technique compliant with those adhered to by molecular biology laboratories. A complete Short Tandem Repeat (STR) panel was obtained using a low initial concentration of extracted DNA. In accordance with radiological analysis, this data confirmed that the skeletal remains analyzed belonged to a European male rather than one of a different ethnicity.

Although STR profiling is preferred due to its discriminatory power, mitochondrial DNA (mtDNA) analysis is often utilized in these cases. A mtDNA analysis was performed with a Mini-Primer Set (MPS) amplification strategy, following the guidelines described by Melton et al., Budowle et al., and Butler.[1-3] The profile, in terms of differences from the Anderson sequence (i.e., the Cambridge Reference Sequence (CRS)), was compared with databases to determine haplotype frequency. This analysis confirmed that the skeletal remains belong to a European man rather than one of a different ethnicity.

Using multidisciplinary forensic recovery methods, the lines of evidence used toward the identification were: (1) radiological investigations for preliminary information; (2) radiocarbon analysis for dating of skeletal remains; (3) biological profile of the remains (STRs and mtDNA); and, (4) statistical analysis of genetic data.

In conclusion, despite the inability to perform a DNA matching test, this study demonstrates the relevance of a multidisciplinary approach that significantly helped in gathering a variety of information that was consistent with the historical findings about the saint's life. There is a strong scientific concordance between these findings and the époque of the saint's existence, sex, and ethnicity.

A103 Infant Bone Health: An Evaluation of Quantitative Ultrasound

Miriam E. Soto Martinez, MA, Harris County Institute of Forensic Sciences, 1885 Old Spanish Trail, Houston, TX 77054; Jennifer C. Love, PhD*, OCME, 401 E Street, SW, Washington, DC 20024; and Weilu Han, MPH, University of Texas Health Science Center, 7000 Fannin Street, Houston, TX 77030*

After attending this presentation, attendees will understand the value of Speed Of Sound (SOS) as a measure of infant bone health.

This presentation will impact the forensic science community by evaluating Quantitative Ultrasound (QUS) as an instrument to measure infant bone health. Evaluating pediatric bone health is an important component of a physical exam, especially when unexpected skeletal fractures are found. Research suggests that QUS is a promising tool for assessing infant bone health.

QUS is a technology which measures the speed (m/s) of an ultrasound wave (SOS) as it travels through bone. Studies have shown that physical and material properties that influence bone strength also influence SOS. Bone Mineral Density (BMD) and elastic modulus are positively correlated with SOS, indicating that greater SOS value is related to greater BMD and stronger bone. Cortical thickness, porosity, and anisotropy have also been shown to affect SOS. Furthermore, significant correlations have been reported between bone strength measured by mechanical testing and SOS. As a result of previous research, this study hypothesizes that SOS is associated with factors that affect bone strength, such as chronic illness and prematurity.

In order to test the hypothesis, a prospective study of infant decedents was conducted. During a nine-month period, all infants ranging from 30 weeks post-menstrual age to one year at the time of death that were autopsied by the Harris County Institute of Forensic Sciences and Texas Children's Hospital were included in the study. For each infant, the following measurements and imaging were collected: SOS measurement of the tibial midshaft, circumference of the leg, digital radiographs of the leg and arm, and a histological sample of an anterior rib and iliac crest. Several measurements were collected from the radiographs, including Tibial Midshaft Diameter (TD), total Cortical Thickness (CT), and Medullary Cavity Diameter (MD). Cortical Index (CI), the cortical thickness/tibial midshaft diameter, was calculated. Additionally, the medical histories and autopsy findings were recorded for each decedent.

Analysis of Variance (ANOVA) and linear regression analyses were used to test the relationship between SOS and bone dimensions and medical history (i.e., chronic illness and/or prematurity). The results show no statistically significant differences in SOS measurements between infants positive for traumatic injury or chronic illness and infants with negative histories. A significant relationship was found between SOS and prematurity (p=.011). Simple linear regression analyses indicated that SOS was significantly related to age (p <.001). After birth, SOS decreased with increasing age until ~3 months of age. After ~3 months of age, SOS gradually increased with increasing age until ~9 months of age, at which point it appears to plateau. Removal of the premature infants from the analysis did not appreciably change the relationship between age and SOS. SOS was also significantly related to estimated gestational age (p=.008), birthweight (p=.005), weight (p<.001), weight for age percentile (p=.004), height (p<.001), length for age percentile (p=.018), and leg circumference (p=.002). When age was included as a covariate, there was a significant association between SOS and CI (p<.001) and MD (p<.001). After removal of chronically ill infants from the analyses, the relationships between SOS and TD (p=.017) and CT (p=.043) became significant. After premature infants were removed from analyses, SOS was only significantly related to height (p<.001) and weight (p=.019).

In conclusion, SOS measurements are significantly affected by growth and health-related factors. The significant association between SOS and bone health factors is consistent with previous research and suggests that QUS is an effective tool for evaluating bone strength in infants. Before QUS may be considered a valid tool for evaluating infant bone strength, more research is needed to identify other factors that may significantly affect bone SOS readings in infants.

Quantitative Ultrasound, Infants, Bone Quality

A104 Reliability of Biomechanical Descriptors to Assess Blunt Force Injuries in the Cranium

Ericka N. L'Abbe, PhD, University of Pretoria, 9 Bophelo Road, Pretoria, FL 0001, SOUTH AFRICA; Steven A. Symes, PhD, Mercyhurst University, 501 E 38th, Erie, PA 16546; Michael W. Kenyhercz, PhD, University of Tennessee, 250 S Stadium Hall, Knoxville, TN 37996; Kyra E. Stull, PhD, Idaho State University, Dept of Anthropology, 921 S 8th Avenue, Stop 8005, Pocatello, ID 83209; Gabriele C. Kruger, MSc, 6 Casa Bari, 574 Jacobs Street, Gezina, Pretoria, Gauteng 0084, SOUTH AFRICA; Marie Christine Dussault, PhD, University of Pretoria, Department of Anatomy, Basic Medical Sciences, Pretoria, Gauteng, SOUTH AFRICA; Leandi Liebenberg, MS, 15 Bentwood, Uys Krige Street, Bloemfontein, Free State 9300, SOUTH AFRICA; Erin Chapman, MS, MA, 501 Kensington Avenue, Buffalo, NY 14214; and Jolandie Myburgh, MSc, Univerist of Pretoria, Room 5-17, Basic Medical Sciences Bldg, 9 Bophelo Road, Pretoria, Gauteng 0001, SOUTH AFRICA*

After attending this presentation, attendees will better understand the reliability of features used to describe and interpret blunt force injuries in the cranium.

This presentation will impact the forensic science community by contributing to knowledge on the reliability of descriptions to evaluate bone fractures associated with blunt force injuries.

The predictable response of human bone to destructive forces has been demonstrated in experimental and observational research.[1-4] Bone fracture variability associated with blunt trauma is a combination of intrinsic and extrinsic factors. Biomechanical descriptions are fundamental to evaluating fracture variation and for interpreting the mechanism of traumatic injuries, but the reliability of biomechanical applications to bone trauma interpretation has rarely been tested on real-life forensic cases.

The purpose of this study is to address the reliability of anthropologists to interpret multiple blunt force injuries to the cranium using nine biomechanical descriptions consistently reported in case reports and published in the literature. Among these are included: minimum number of impacts; internal surface radiating fractures; internal surface angled-bevel (failure in compression); external scratch on the bone's surface; chipping of bone; depression or distortion of outer bone contour (failure in external tension); and radiating fractures. Six crania with previously categorized blunt force injuries were randomly selected from the evidentiary archives of cold cases in the Department of Anatomy at the University of Pretoria, South Africa. Six observers, who ranged in bone trauma experience from none to greater than 20 years, were provided with both written definitions and photographs, documenting the above-mentioned variables. Only the two observers had prior knowledge of the cases. All variables were scored following a dichotomous system (present or absent). The scores were summed into a "total trauma score" for each skull and each observer.

Percent agreement was used to evaluate the reliability of each feature among all six observers. A Total Trauma Score (TTS) was also created for each observer. The TTS acted as a component score for all traits for each cranium. An Intra-Class Correlation Coefficient (ICC) was used as an index of inter-rater reliability.

Depression or distortion of bone (plastic deformation) and external scratch on the bone's surface were the most reliable with percent agreements at 98.9%, followed with chipping of bone at 88.9%. The remaining traits ranged between 70% and 78%. The ICC for TTS was 78% (p-value=0.001) and had a 95% confidence interval of 36%-96%. When separated by experience, the observers with the most years of experience showed the most disparity among TTS (ICC=58%) and the observers with the least years of experience had less disparity among TTS (ICC=71%).

Knowledge of basic biomechanics and fracture pattern recognition is key to accurate interpretation of trauma in the human skeleton. Additionally, bone trauma interpretation is a complex, multifactorial process not easily amenable to statistical analysis. Yet, when biomechanical descriptions are evaluated within a dichotomous system, a comparison of bone trauma trait analysis among anthropologists of varying experiences is possible. Overall, the biomechanical descriptions are repeatable among observers of various experiences. Experience (in years) did not seem to positively affect the ICC, but bias may exist as some of the experienced observers had previous experience with the material.

The findings offer support for the use of the biomechanical approach to describe, analyze, and interpret traumatic injuries in bone. Within a biomechanical framework, observations related to blunt trauma interpretation are more likely to be reliable than simply classification methods. Future studies will include descriptions of ballistic injuries and will address the definition/refinement of blunt traits with lower reliability.

Accurate interpretation of fracture characteristics is necessary for communication among scientists, in education, and in reports submitted to a court of law.

MacGregor, MSc, Queensland University of Technology, School of Biomedical Sciences, Faculty of Health, Gardens Point Campus, Brisbane, Queensland 4001, AUSTRALIA*

After attending this presentation, attendees will appreciate: (1) the benefits of a semi-automated protocol to conduct volumetric measurements of complex skeletal elements using tissue density-based voxel-processing of computed tomography scans; and, (2) the presence of sexual dimorphism in frontal sinus volume in subadults.

This presentation will impact the forensic science community by advancing understanding of subadult frontal sinus development through the use of 3D reconstructed Multi-Slice Computed Tomography (MSCT) scans. This research will also reinforce the invaluable nature and varied applicability a contemporary virtual skeletal repository offers to both forensic anthropology and osteoarchaeological fields of research.

Due to high probability in the recovery of the frontal bones within fragmented remains, comparison of frontal sinus morphology in antemortem versus postmortem radiographs are routinely conducted for personal identification in forensic casework. While sexual dimorphism in frontal sinus size has been widely reported in adults, there is currently no research signifying the age of onset of sexual dimorphism in morphometric analyses of the frontal sinuses in subadults. Accordingly, this study seeks to establish a temporal profile of frontal sinus development and determine the timing of sexual dimorphism of the frontal sinus volume in a contemporary population of Australian subadults, using a standardized 3D modeling protocol.

A total of 89 cranial Digital Imaging and Communications in Medicine (DICOM) datasets (males: n=45, females: n=44) aged 6 years to 19 years were accessed from the Skeletal Biology and Forensic Anthropology Virtual Osteological Database and imported into an advanced visualization software to generate an isosurface model and segmented masks of the right and left frontal sinuses.[1] A semi-automated method for volumetric calculation was developed to produce a standardized protocol for frontal sinus segmentation based on material discriminatory voxel intensity values. Voxels with intensity values ranging from -1,000 to 150 Hounsfield Units (HU) were selected, corresponding to the tissue density of air, fibrous connective tissue, cellular debris, and mucous that may be contained within the sinus cavity. Frontal chord (Bregma-Nasion) measurements were also conducted to standardize the crania, accounting for individual variability in cephalic size.

Intra- and inter-observer testing was conducted on three sample datasets obtained from randomly selected individuals of varying ages. Intra-observer error demonstrated high precision and consistency between repeated measurements with a mean percent Technical Error of Measurement (%TEM) of 3.15% and Intra-Class Correlation Coefficient (ICC) of 1.00 (Confidence Interval (CI)=0.992-1.00). Similarly, inter-observer reliability demonstrated a high degree of observer agreement despite varying anatomical and radiographic experience, with a mean %TEM of 1.26% and ICC of 0.99 (CI=0.991-1.00). Age and sex effects were analyzed using independent Student t-tests with relevant post-hoc tests.

The preliminary results of this study show a significant expansion of normalized total frontal sinus volume from 6 years to 16 years of age from 7.20±1.75 mm^2 to 99.84±13.16 mm^2 and 12.85±2.91 mm^2 to 65.64±10.49 mm^2 in Queensland males and females, respectively (P <0.01), with the greatest growth velocity occurring between 12 years and 16 years (P ≤0.01) represented by a 2- and 3.6-fold increase in males and females, respectively. Sexual dimorphism of frontal sinus volume was prominent from 12 years of age, with males exhibiting greater absolute and normalized volume than females in the 12 year-13 year, 15 year-16 year, and 18 year-19 year cohorts (P ≤0.05). This is markedly later than that reported in a recent *in silico* study investigating maxillary sinus volume in a Malay population which demonstrated the presence of significant sexual dimorphism after the 6th year.[2]

Interestingly, the data also revealed a 9% bilateral and 3% unilateral absence of the frontal sinuses. Bilateral absence was highest in the 6 year-7 year age cohort, suggesting later pneumatization timings than previously recorded. This presentation highlights the use of voxelization-based *in silico* volumetric approaches to quantify irregular skeletal structures based on their tissue composition. This study provides the first insight into the complex morphological and volumetric changes of the frontal sinuses that occur with age in the cranium of Australian children. Classification accuracies using discriminant function analysis for subadult age estimation of individuals aged 6 years to 25 years of age as a new tool biological profile in contemporary subadults will also be discussed.

A106 Estimating Age in Juvenile Crania Using Cranial Vault Thickness (CVT)

Kelly R. Kamnikar, BS, Mississippi State University, PO Box AR, Mississippi State, MS 39762; Nicholas P. Herrmann, PhD, Mississippi State University, Cobb Inst Archaeology, Box AR, Dept of Anthro & Mid East Cultures, Mississippi State, MS 39762; Pierre M.M. Guyomarc'h, PhD, International Committee of the Red Cross, Mansour Bldg, Sadat Street, Hamra, Beirut, LEBANON; and Molly K. Zuckerman, PhD, Mississippi State University, Dept of Anthro and Middle Eastern Cultures, Box AR, Mississippi State, MS 39762*

After attending this presentation, attendees will better understand a novel technique of aging juvenile skeletal remains using CVT.

This presentation will impact the forensic science community by offering an alternative technique for aging unknown juvenile skeletal remains.

Age estimation, a component of the biological profile, contributes significantly to the creation of a postmortem profile of an unknown set of human remains, which can aid forensic professionals in linking remains to a missing person's profile. The goal of this study is twofold: (1) to introduce a new juvenile age estimation technique using CVT; and, (2) to compare CVT age estimation in an unknown individual with dental development, a more reliable technique.

Data for this study comes from Computed Tomography (CT) scans (n=74, 37 males and 37 females) of living children in Paris and Bordeaux, France. These scans come from individuals aged newborn to 16 years old and from different ethnic backgrounds. CVT was measured at five craniometric points (nasion, glabella, bregma, lambda, and opisthocranion) that have previously shown correlations between CVT and age, using the Half Maximum Height (HMH) function of the Treatment and Increased Vision for Medical Imaging (TIVMI) software.[1,2] HMH values provide an optimized interface between the tissues (air, soft tissue, bone, etc.) with high accuracy, based on the Hounsfield units of the CT scan. Multivariate Adaptive Regression Splines (MARS) models, using LOcal regrESSion (LOESS) regression, were created to illustrate the relationship between cubed root of known age and CVT in the open-source statistical software, R. A Prediction Interval (PI) was created for each point from each of the models.[3]

Results from this study indicate that CVT data vary in their predictive ability for age by location. CVT data for nasion and glabella do not conform to normality tests, which was further reinforced by visual examination of the Quantile-Quantile (QQ) plots. Models at bregma, lambda, and opisthocranion were normal and indicated that the models fit the data. PIs at bregma varied by 0.4mm, a difference that cannot be reliably used as an age indicator. PI values for lambda range from 0mm to 3mm in thickness and values for opisthocranion range from 0mm to <4mm.

The PIs were then used to assess age in an unknown juvenile cranium, from the Mississippi State Medical Examiner's Office in Jackson, MS. CVT was measured by manually calculating HMH values on a radiograph in ImageJ. These values were compared to PIs created from the models, and low, high, and mean values were produced at the 95% and 85% PI.

At the 95% PIs, predicted values for both lambda (2.214 years to 17.704 years with a mean age of 7.469) and opisthocranion (0.848 years to 22.778 years with a mean age of 6.762) are very large. The mean values remained the same at the 85% PIs, but the ranges narrowed to 3.2175 years to 14.4074 years for lambda and 1.715 years to 17.254 years for opisthocranion. Age estimation using transition analysis of dental development produce an age range of 3.811 years to 7.839 years with a mean age of 5.509 years old.[4]

Comparison of the two methods indicates that the PIs for age estimation using CVT at lambda and opisthocranion are large. The PIs for opisthocranion reach into early adulthood. Results also show that aging by CVT overestimates juvenile age at both points, although the mean at lambda is more overestimated. Aging by CVT is not as accurate as aging by dental development. Aging by CVT could benefit from additional known-age samples in model and PI creation. A larger sample could possibly narrow PIs and make estimates more reliable.

Age Estimation, Juvenile, Computed Tomography

A107 Correlation Between Body Size and Intracranial Capacity in Korean Youth

Jae gul Suh, MD, Department of Anatomy, Korea University College, Inchonro 73, Sungbuk gu, Seoul, SOUTH KOREA; Yesel Kim, MD, Department of Anatomy, Korea University College, Inchonro 73, Sungbuk gu, Seoul, SOUTH KOREA; Dasom Kim, BA, Department of Anatomy, Korea University College, Inchonro 73, Sungbuk gu, Seoul, SOUTH KOREA; In Sung Park, PhD, Department of Emergency Medicine, Kyungil Univers, 50, Gamasil-gil, Hayang-eup, Gyeongsan, SOUTH KOREA; Nam Joon Lee, MD, PhD, Department of Diagnostic Radiology, Korea Univers, Inchonro 73, Sungbuk gu, Seoul, SOUTH KOREA; and Im Joo Rhyu, PhD, Department of Anatomy, Korea University College of Medicine, Seoul, SOUTH KOREA*

After attending this presentation, attendees will understand how to estimate the intracranial capacity from body size and vise versa.

This presentation will impact the forensic science community by providing estimation equations between body size and intracranial capacity.

Cranial capacity is an important parameter in the fields of evolutionary biology and anthropology and is closely related to brain size. Therefore, cranial shape and capacity are important parameters in evolutionary research, physical anthropology, and forensic sciences.

Four methods are currently available to obtain intracranial volume: (1) a balloon and water filling method; (2) cephalometric measurements and calculations based on estimation equations; (3) the small grain-packing method; and, (4) measurements based on radiological tools, including computed tomography and Magnetic Resonance Imaging (MRI). In this study, 3D modeling of intracranial volume based on MRI data obtained from living subjects was used, not dry skulls of unknown origin.

The subjects were recruited through advertisements at the Korea University web page and local community newspapers. The research purpose and procedures were fully explained to the subjects. History taking (including alcohol consumption) and physical examination were performed by a neurologist of the Korea University Medical Center. MRI was performed on a 1.5-Tesla Magnetom vision after measuring body height and weight. The Digital Imaging and Communications in Medicine (DICOM) format data were imported into the V-work 3.5 program. The MRI signal of the cranial bone was identified under the direction of a radiologist, the intracranial 3D volume model was constructed, and the volume was calculated automatically by the program based on voxel information.

The relationships of body height and weight with intracranial capacity volume differed according to sex. The intracranial capacity volume was correlated with body height in males (R=0.39, p <0.05), but not in females (R=0.24, p >0.05). The correlation coefficient for intracranial capacity and body height markedly increased to R=0.71 (p <0.01) when male and female subjects' data were combined. Conversely, intracranial capacity (volume) correlated with body weight in females (R=0.38, p <0.05), but not in males (R=0.16, p >0.05). The correlation coefficient of body weight and intracranial capacity volume reached R=0.63 (P <0.01) when the data from all subjects were included in the analysis. Further stepwise linear regression analyses revealed that body height is a key variable for intracranial capacity volume, which can be expressed by the following equation: intracranial capacity volume (cm^3)=(11.440 x body height)–420.03, R^2=0.51. The overall correlation coefficient between intracranial volume and brain volume is 0.894 (P <0.01), and linear regression provides the following equation: brain volume (cm^3)=58.3+(0.84 x cranial capacity), R^2=0.795.

In this study, it was shown that intracranial capacity in Korean youth is significantly influenced by body height, and intracranial capacity strongly correlated with whole brain volume. These data will be used to characterize physical anthropological aspects of Koreans and provide a useful tool for forensic application.

Skull Capacity, Body Weight, Body Height

A108 Estimating Body Composition From Stature and Bi-Iliac Breadth in Modern Young Adult United States Populations (NHANES III)

William C. Schaffer, MA, 13229 S 48th Street, Apt 3042, Phoenix, AZ 85044*

After attending this presentation, attendees will have a better grasp of the fidelity to estimate total body mass, fat-free mass, and fat mass from stature and bi-iliac breadth in modern United States individuals and human skeletal remains as well as some of the factors that impede the accuracy of body composition estimates using the stature and bi-iliac breadth technique.

This presentation will impact the forensic science community by supplying an accurate method to estimate body composition for use in forensic anthropology and the potential for the inclusion of body composition estimates in the biological profiles of unidentified human remains for use in medicolegal investigation and human identification.

Often estimates using the stature and bi-iliac breadth technique for total body mass are not presented in biological profiles for use in forensic anthropology because: (1) there is a lack of population- and sex-specific equations for modern individuals; and, (2) many studies using existing techniques to estimate body mass of modern individuals with known mass are inaccurate.[1–7] Recently, greater confidence has been demonstrated in estimating total body mass from stature and bi-iliac breadth using modern young adults (20 years to 39 years of age), but only in individuals with health body fat percentages.[8] Thus, a major caveat when employing the stature and bi-iliac breadth method to estimate total body mass in modern individuals is both age and excess body mass that deviates from healthy norms.[3,8,9]

Body composition was estimated using stature and bi-iliac breadth from 5,555 individuals in six population samples, males and females, who self-identified as non-Hispanic United States White, non-Hispanic United States Black, and Mexican American from the Third National Health and Nutrition Examination Survey (NHANES III) 1988–1994.[10] Fat-free mass was estimated using values extracted from bioelectrical impedance analysis.[11] The population samples were segmented into sub-samples representing groups with healthy body fat percentages as recommended by the American Council on Exercise (ACE) and groups with increments of +5%, +10%, +15%, and +20% body fat above the healthy norm.[12-13] Ordinary least squares regression was conducted for each sub-sample (108 total) using total body mass, fat-free mass, and fat mass as the dependent variables, and stature and bi-iliac breadth independent variables.

The general pattern observed in this study is that when estimating total body mass, with increasing body fat percentages beyond ACE standards, the influence of stature decreases while the influence of bi-iliac breadth increases substantially. When estimating fat-free mass, the estimates are approximately the same in terms of the influence of stature and bi-iliac breadth, even when using various body fat percentages. Noticeably, this pattern is more consistent in males than females for all population affinities. The overall interpretation of this trend is that fat-free mass can be more accurately estimated from stature and bi-iliac breadth irrespective of body fat percentage and that the primary signal in body composition estimation using the stature/bi-iliac breadth method is fat-free mass. Additionally, prediction of fat mass appeared to be the least accurate in individuals with healthy body fat ranges, and increasingly more accurate only when body fat percentage was elevated and fat mass made up a greater proportion of total body mass.

Three ways to estimate total body mass in human skeletal remains using stature and bi-iliac breadth are proposed. First, total body mass can be estimated assuming both that the individual is a young adult (20 years to 39 years of age) and with body fat percentage within a healthy range.[8] Second, fat-free mass can be estimated, then various ranges of body fat percentages can be presented to achieve incremental total body mass estimates. Or third, fat-free mass can be estimated, then modeled expectations of fat mass in healthy individuals that coincide with stature and fat-free mass can be predicted.[14–16]

The results of this study continue to support the stature/bi-iliac breadth method as an accurate technique to estimate not only total body mass, but now also body composition components such as fat-free mass and by indirection fat mass; however, most estimations assume the individual is a young adult and has healthy body fat percentage. The method presented provides a new reliable tool to estimate body composition for inclusion in biological profiles to aid to the process of human identification in forensic anthropology and medicolegal investigation.

A109 Estimation of Stature From the Foramen Magnum Region in an American Population: A Validation Study

Margarita M. Villarreal, BS, 707 Eucalyptus Street, Ontario, CA 91762*

After attending this presentation, attendees will understand how new univariate and multivariate linear regression formulas were developed for the American White population for the determination of stature from the foramen magnum region.

This presentation will impact the forensic science community by providing a new method to estimate stature using the foramen magnum area for the American White population. While the traditional long bone methods are better for stature estimation, this new technique does provide a reasonable stature estimation range. Thus, if only the cranium is found, a complete biological profile can be assessed.

In forensic cases, complete human remains are not always found, making the ability to estimate stature from bony elements other than long bones important. This validation study focused on Cui's and Zhang's method for the estimation of stature using the foramen magnum region developed for China's Northern and Southern male populations.[1] This study addresses two main research questions: (1) can Cui's and Zhang's regression formulas for Chinese persons of unknown birthplace be used to significantly estimate stature in an American White population; and if not, (2) can new linear regression equations be developed for American White males and females in order to estimate stature within a reasonable margin of error?

Using Cui's and Zhang's 11 parameters from the foramen magnum area and William Bass Donated Skeletal Collection at the University of Tennessee, Knoxville, modern crania from American White females (*n*=137) and American White males (*n*=135) were measured. Age at death varied between females (29 years to 89 years old) and males (26 years to 96 years old). Tests indicate that the regression formulas for Chinese persons of unknown birthplace estimated stature better for females than males, but not significantly. Thus, new simple linear regression formulas representing univariate and multivariate equations were created for American White females and males.

American White females had an interval of Standard Error Of Estimation (SEE) of ±6.32cm to ±6.53cm, with an SEE of ±5.66cm to ±5.95cm for males. Correlation coefficients between stature and measured parameters were different in males and females, except for the Maximum Interior Distance (MxID) between condyles. Blind tests using 40 cranial measurements not used in the creation of the new regression formulas were tested on the new equations for males (*n*=18) and females (*n*=22). When estimated stature is not adjusted for age at death, 77% of total female test cases had their estimated stature fall between 0cm to ±10cm of their recorded stature, and 92% of total test cases fell between the 0cm to ±15cm interval. The same percentages occur when age at death is used to adjust estimated stature in the female test cases; however, this is slightly different for males. When age at death is not used to adjust estimated stature, 72% of total male test cases had their estimated stature fall between 0cm to ±10cm from their recorded stature; when the adjustment is made, a 2% increase is seen with 74% of total cases occurring in the same cm range. In addition, 93% of total male cases had their non-adjusted estimated stature fall between 0cm to ±15cm from their recorded stature; when the adjustment is made, a 2% decrease is seen with 91% of total test cases falling in the same cm range. In addition, inter- and intra-observer tests for reliability conducted showed that only the MxID parameter was poorly reliable when measured with an inter-observer ICC2,1 of 0.254.

In conclusion, this validation study found that the foramen magnum region could not significantly be used to reliably estimate stature; however, in cases where only the cranium is found, it can be used with some accuracy as it is the only cranial method available for the American White population.

Stature Estimation, Cranium, Foramen Magnum

A110 Examining Four Potential Proxies for Standard Craniometrics: A Statistical Analysis for Significance and Demographic Correlations

Jacob L. Cheramie, 3410 Severn Avenue, Apt 521, Metairie, LA 70002; and Maranda A. Kles, PhD, University of Louisiana at Lafayette, PO Box 40198, Lafayette, LA 70504*

After attending this presentation, attendees will recognize the potential for the development of proxy measurements for standard craniometrics and the need for novel craniometrics. This study presents an evaluation of proxy measurements for Upper Facial Breadth (UFB) and a novel measurement for interorbital distance.

This presentation impacts the forensic science community by providing an alternative method for ascertaining UFB in fragmented remains and presents a potential new cranial measurement. Both of these measurements contribute to the identification of sex and ancestry of human skeletal remains in forensic cases.

Following the contemporary trend in the discipline of forensic anthropology to re-evaluate standard craniometrics and add statistical rigor to the assessment of sex and ancestry, this preliminary research tests three potential proxy measurements for UFB and one potential proxy measurement for interorbital breadth. These proxies would be used for fragmentary remains in which the pristine standard craniometrics are unobtainable.

The three UFB proxies are based on a unilateral measurement from nasion to Frontomalartemporalis (FMT) multiplied by two; one is measured in the same plane ("Planar"), one is measured across the plane ("Cross-planar"), and the last is measured with an instrument ("Apparatus") created for this study. The proxy for interorbital breath was the measurement of distance between the orbits at the height of nasion, as opposed to the standard dacryon-to-dacryon measurement. These measurements were then compared to their standard measurements. Standard craniometrics and the four proxy measurements were collected on 30 individuals, most with known demographics.

Fluctuating asymmetry was assessed and found not to be a factor in the study population. The proxies were then tested for significant difference from their standard counterparts. All measurements were found to be significantly different from the standard, except the "Planar" measurement. The "Planar" proxy and UFB were assessed by discriminant function analysis for their ability to discriminate between the sexes and between the ancestral groups "White," "Black," and "Native American" in both Statistical Package for the Social Sciences (SPSS) and FORDISC®. Analysis shows that "Planar" was as effective as UFB in discriminating sex and ancestry. Based on these results, it appears that the "Planar" measurement is an effective proxy for UFB. Additional testing is needed to further bolster these results.

Testing found the measurement of interorbital breadth at the height of nasion was significantly different than the standard interorbital breadth measurement. Preliminary testing indicates that this novel measurement may, nonetheless, be useful in the assessment of sex and ancestry much like the standard interorbital measurement, but further testing of this finding is needed.

Proxy, Sex, Ancestry

A111 The Effects of Household Corrosive Chemicals on Pig Bones and Human Tissue

Gina E. Baglieri, 160-17 59th Avenue, Flushing, NY 11365*

After attending this presentation, attendees will better understand: (1) how household corrosive chemicals cause decomposition on pig bones and human tissue; and, (2) if altered bones decompose faster than unaltered bones.

This presentation will impact the forensic science community by providing results from a two-part experiment that both attempts to validate previous research as well as adds a new element that has not previously been studied. This presentation will add to our databank of knowledge about the effects corrosive chemicals have on the body.

One of the most important goals in forensic anthropology is to provide information leading to the positive identification of a victim. Positive identification can be challenging because attempts to hide the identity of a victim are frequent. One way to hide a person's identity is the application of household chemicals to a body. These easily obtainable substances may be used to disfigure a body by dissolving the soft tissue and causing it to appear different than it did previously. In recent studies, the effects of corrosive chemicals have been tested on human teeth, bones, hair, and nails. In an experiment by Cope and Dupras, the effects of household corrosive chemicals on human dentition were examined.[1] For the present study, four corrosive chemicals were used: hydrochloric acid, sulfuric acid, phosphoric acid, and sodium hydroxide. The results of this experiment suggest that hydrochloric acid was the most destructive. Similar results are seen in the study by Hartnett et al.[2] The present study examined the effects of household corrosive chemicals on human teeth, hair, nails, and soft tissue. The chemicals included were hydrochloric acid, sulfuric acid, household lye, bleach, and the soft drink Coca-Cola™. The hydrochloric acid was the most destructive agent, fully consuming all tissue in less than 24 hours.

The objective of this research was to study the effects of everyday, household corrosive chemicals on pig bones, human hair, and human nails. The common chemical names and their main ingredients (in parentheses) used in all trials were: Acidic Toilet Bowl Cleaner® (hydrochloric acid), Lime-Away® (sulfamic acid), Septic Tank Cleaner® (hydrogen peroxide), Heavy Duty Stripper and Cleaner® (sodium hydroxide and diethylene glycol monobutyl ether), and Pequa Drain Cleaner® (potassium hydroxide). Water was used as the control. In order to meet the objective, this study consisted of two experiments. The first included recording the effects of the chemicals on the bones, hair, and nails for an extended period of time. The second included recording the effects of the chemicals on altered pig bones. Alterations included burnt, frozen, and chopped bone segments. After an initial pilot study, it was hypothesized that the altered bones would dissolve and change faster than the unaltered bones.

The most destructive chemical tested was the Pequa Drain Cleaner®, which contains potassium hydroxide. It caused the fastest dissolution rate on the burnt bone segment in Experiment #2, causing the bone to become bone residue in only 24 hours. Changes were also seen in both experiments by other chemicals such as the Acidic Toilet Bowl Cleaner®, where the most significant change was also seen in the burnt bone in Experiment #2. A rapid rate of mass loss was recorded from 6.8 grams to 5.9 grams in the first 24 hours. The altered bones dissolved or changed appearance at a faster rate than the unaltered bones, which supports the hypothesis.

Research on the effects of corrosive chemicals can help forensic anthropologists identify cases involving corrosive chemicals and can provide a foundation to direct future research. This research addressed the lack of data on the effects of chemicals on frozen, burned, or cut-up bones, and validated the research by Hartnett et al.[2] It can also be concluded that certain alterations to the bone play a significant role in dissolution rate and overall physical damage to the bone.

Forensic Anthropology, Corrosive Chemicals, Decomposition

A112 Direct and Indirect Blunt Force Trauma on the Cranium: Any Visible Differences

Kathryn Sloper, BS, Liverpool John Moores University, Byrom Street, Liverpool, Merseyside L3 3AF, UNITED KINGDOM; Constantine Eliopoulos, PhD, Liverpool John Moores Univ, School of Nat Science & Psych, James Parsons Bldg, Byrom Street, Liverpool L3 3AF, UNITED KINGDOM; and Matteo Borrini, PhD, Liverpool John Moores University, RCEAP-School of Natural Science & Psych, Byrom Street, Liverpool L3 3AF, UNITED KINGDOM*

After attending this presentation, attendees will have a better understanding of the possibility of discriminating between the types of cranial fractures resulting from blunt force trauma produced by direct and indirect strikes.

This presentation will impact the forensic science community by providing an empirical experiment model to understand the mechanics of fractures produced as a result of blunt force cranial trauma when the force is applied in both a direct and indirect way.

The majority of studies on the infliction on blunt force trauma to the cranium use mechanical methods (e.g., drop hammers) to produce fractures. These tools require adjustments of both the specimen, to allow for trauma to be inflicted to specific regions, and the amount of force necessary to produce a fracture with each strike.

The goal of this preliminary study was to create an experimental model with participants that inflict blunt force trauma to produce a more realistic fracture pattern.

Twenty adult pig heads (*Sus scrofa domesticus*) were struck with a 16-ounce claw hammer by five right-handed male participants between 20 years and 25 years of age. Specimens were placed in a custom-designed denim bag housed within a holding frame securely suspended by ratchet straps. Each skull was assigned an individual identification code based on both the type of strike (direct or indirect) and the sequence in which trauma was inflicted. For the purpose of this study, a direct strike refers to an over-the-head strike from the right-hand side of the body and an indirect strike refers to an over-the-head strike from the left-hand side of the body. The participants were instructed to strike the frontal region of four pigs' heads using the flat rounded surface of the hammer; two heads were struck using a direct overhead strike and the remaining two heads using an indirect overhead strike. After hot-water maceration, a visual analysis of fractures was performed by comparing with images and descriptions published in previous studies.[1-3]

A total of 16 fractures were observed (average length 42.9mm, width 31.0mm), and the number of lesions produced by indirect strikes (n=9) appear to be larger than direct strikes (n=7). This trend seems to be statistically not significant, but the small sample size must be taken into consideration. A larger sample, for example, may help to discriminate between the types of strike inflicted. Further research involving a quantitative measuring tool (e.g., accelerometer) could also improve the understanding of the dynamics of the force applied to produce trauma.

An additional outcome of this preliminary study is the creation of a flowchart as a supporting tool to identify the fracture type in a more objective and reliable way. The flowchart allows classifying five different types of fractures (linear, superficial depressed, depressed, comminuted, and depressed comminuted) according to the macroscopic characteristics observed on the bone.

Presented here is a pilot study that, even if limited by the small sample size, demonstrates the potential of an empirical experiment and provides an intuitive flowchart that describes the features of the fractures produced as a result of blunt force trauma. Furthermore, this flowchart has the potential to be a more objective method for the description of injuries which could be shared by forensic practitioners.

Cranial Fracture, Blunt Force Trauma, Biomechanic

A113 A Method of Sex Determination From the Scapula in Modern American Forensics

Melissa K. Kuhn, 5548 Taft Drive, San Jose, CA 95124; Ismail M. Sebetan, MD, PhD*, National University, Forensic Sciences Program, 11255 N Torrey Pines Road, La Jolla, CA 92037-1011; and Amy Zimmer, MS, 1401 Broadway, San Diego, CA 92101*

After attending this presentation, attendees will understand the need for alternative skeletal sexing methodologies and that sexually dimorphic characteristics can be temporally and/or ethnically specific. In addition, attendees will learn that these changing characteristics can also affect discriminant function accuracies over time.

This presentation will impact the forensic science community by offering a new discriminant function method for determining the sex of human skeletal remains from the scapula, thereby allowing construction of a biological profile in which more commonly used skeletal elements (e.g., skull and pelvis) are unavailable.

One of the major goals of the forensic anthropologist is to describe an individual's biological profile, which includes at the minimum sex, stature, age at death, and race.[1] When describing the biological profile, sex determination is completed first because other traits such as stature and age at death can be related to sex.[2] Determining the sex first when building the biological profile is not only important in helping determine other aspects of the profile, but it reduces by half the number of possible unknown individuals needed for comparison.[3] This is especially helpful since the biological profile created by forensic anthropologists is a tool to define as small a group of possible matching individuals as possible from a large group of possible victims and missing persons.[4]

Human skeletal remains are often found fragmented or incomplete. In these situations, postcranial elements such as the scapula are utilized in sex determination and identification methods. A previous study had found that a discriminant function using measurements of the scapula was applicable to a late 19th-early, 20th-century American population. The objectives of this study were to explore if the previous function was still applicable to a more modern American population, if a new, more accurate function could be developed, and if there were any ethnic subgroupings occurring in the United States that could be identified.

This study utilized data from the Forensic Data Bank collected by the University of Tennessee; the previous function was tested and a new discriminant function was developed. The results indicate that both functions can be applied to a modern American population. The previous function achieved an accuracy of 92.4% and the function from this presentation achieved an accuracy of 92.1%. Also, tests were performed to determine if significant ethnic subgroupings were occurring in the study's population data. There were not any significant differences found in the scapular measurements between the White, Hispanic, and Black subgroupings.

Sex Determination, Scapula, Data Bank

A114 Sex Classification in a Sample of American Whites Using Interlandmark Distances of the Zygomatic Bone and Standard Cranial Measurements

Sarah M. Furnier, 1487 E Hull Road, Hope, MI 48628; and Stephen D. Ousley, PhD, Dept of Anthropology/Archaeology, Mercyhurst University, 501 E 38th Street, Erie, PA 16546*

After attending this presentation, attendees will understand a method of sex classification based on Interlandmark Distances (ILDs) of the zygomatic bone in combination with standard cranial measurements as well as the classification rates achieved in a sample of American Whites.

This presentation will impact the forensic science community by introducing a method of sex classification based on measurements of the zygomatic bone with cross-validated classification rates. This presentation will add to current research by providing an understanding of the utility of ILDs and sexual dimorphism in the zygomatic region of the cranium in sex classification.

Sex classification is a crucial part of estimating the biological profile of an unknown individual. Following the *Daubert* Supreme Court decision, an increased emphasis has been placed on the validation of traditional forensic anthropological techniques, including those for sex estimation, and on the development of statistically sound methods.[1,2] After an extensive literature search, it was found that little has been done with sex classification using metrics of the zygomatic bone. Bizygomatic breadth is generally regarded as one of the best indicators of sex, and previous publications have shown that differences between the sexes do exist in the upper face and zygomatic regions and have obtained high sex classification rates using measurements in these regions.[3,4] Therefore, it is clear that significant sexual dimorphism exists in this region of the cranium. The goal of this study was to determine if ILDs could be used to capture the sexual dimorphism present in the zygomatic and to evaluate whether or not these ILDs, in combination with standard cranial measurements, could accurately classify sex in an American White sample.

ILDs have been shown to be good group discriminators and have been used in the past to successfully estimate ancestry.[5,6] Linear Discriminant Function Analysis (LDFA) has been utilized heavily in metric sex estimation techniques from very early on in the development of metric sex estimation methods.[3,7] In this study, ILDs of the zygomatic bone in combination with standard cranial measurements were analyzed using LDFA in order to examine sexual dimorphism of the zygomatic bone and facial region and to evaluate the sex classification rate in a sample of American Whites from the Terry Collection. FORDISC® 3.1 was used to perform LDFA using stepwise selection to identify the best variables for classification and to provide cross-validated classification rates.[8,9]

Ten measurements — JUB, zygom to zyts, jug to zygoo, zygom to zygoo, fma to zyti, fmt to zygom, jug to zyts, mpl to zygom, fma to zygoo, and ZMB — were stepwise selected using LDFA. An overall classification rate of 82.7% was achieved. Females classified better with 86.5% accuracy in comparison to males at 78.9%. Another LDFA analysis using only unilateral ILDs yielded a classification rate of 78.5%, with females classifying at a rate of 73.7% and males at 82.9%. Five measurements — zygoo to zyti, mpl to zygom, fma to zyti, jug to zygom, and fma to zyts — were stepwise selected in this analysis. In general, the measurement means for males were significantly greater than those for females, except in the case of two ILDs, which were not significantly different between the sexes. Shape analysis resulted in a lower classification but selected variables that reflected width, height, and curvature differences, indicating that there are some shape differences between the sexes.

In conclusion, the results of this study provide evidence that sexual dimorphism does exist in the zygomatic bone. When ILDs of the zygomatic are used, in combination with standard cranial measurements or on their own, this sexual dimorphism can be useful in sex estimation.

Biological Profile, Zygomatic, Interlandmark Distances

A115 Differential Taphonomy Based on Microenvironment: The Case of Botanical Boy

Kevin M. Lougee, DO, Denver Office of the Medical Examiner, 660 Bannock Street, Denver, CO 80204; James Louis Caruso, MD, OME, 660 Bannock Street, Denver, CO 80204; Meredith A. Lann, MD, Denver OME, 660 Bannock Street, Denver, CO 80204; and Laura A. Regan, PhD, Headquarters United States Air Force Academy, Department of Biology, 2355 Faculty Drive, Ste 2P389, USAFA, CO 80840-6226*

After attending this presentation, attendees will better understand how seemingly minor differences in environment, such as the presence of textiles, can dramatically affect decompositional and taphonomical processes in human remains.

This presentation will impact the forensic science community by providing a unique example of differential taphonomy in a singular burial and offering those involved in human remains recovery and analysis points to consider when approaching potentially similar cases.

The lush area now known as the Denver Botanical Gardens and Cheesman Park, Denver, CO, was originally established in 1859 as the Mount Prospect Hill Cemetery, but due to poor management, disrepair, and alternate ideations for the purpose of the land, interments were largely halted in 1893. Bodies were moved to alternate locations within the city, but graves were poorly marked and burial records virtually non-existent; thus, many decedents remained where they were initially laid to rest.

In October of 2012, human remains were discovered while road construction and irrigation drainage repair were being performed adjacent to the Denver Botanical Gardens. Multiple exhumations were conducted over the following week to include the removal of the remains belonging to a child, estimated at approximately eight years of age at time of death. Coffin hardware and bits of wood were recovered in association with the child. The remains were skeletonized with minor amounts of mummified tissue adherent in the forearm regions. The cranium was present with light-colored hair affixed, combed, and parted. Additionally, the individual was fully clothed in knickers and a jacket (not uncommon dress for young boys of this period) with the suit in exceptional condition. While no headstone was recovered in association with this individual, headstones recovered nearby during this disinterment effort dated from 1878 to 1885. It is not uncommon to find well-preserved skeletal remains owing to the arid climate of the "Mile High City." What is exceptional is to find intact clothing dating back to the 1880s.

The remains were housed in cold storage at the Denver Medical Examiner's Office and were recently examined and fully cataloged so that the unidentified individual may be reinterred locally. The elements in direct contact to the burial environment were quite well preserved; however, those encased within the clothing demonstrated a completely different taphonomy. Large amounts of insect frass were recovered external and internal to the suit. More importantly, the thoracic and appendicular elements contained inside the clothing were delaminated and friable with significant degradation of most cortical surfaces. The slightest movement of these bones led to the osseous material crumbling in place.

This presentation will consider the possible mechanisms behind this differential preservation and what this means to the modern forensic practitioner.

Differential Taphonomy, Microenvironment, Disinterment

A116 Students in the Forensic Laboratory: Fostering Education While Maintaining Quality

Christiane Baigent, MSc, Metropolitan State University Dept Sociology/Anthr, PO Box 173362, Campus Box 28, Denver, CO 80217-3362; and Catherine M. Gaither, PhD, Osa Field Institute, 2066 E Mineral Avenue, Centennial, CO 80122*

After attending this presentation, attendees will have a good understanding of a model for integrating student participation into the forensic laboratory without compromising the probative value of evidence.

This presentation will impact the forensic science community by serving as a tested model for educators seeking to integrate field and laboratory experience into their curriculum, thereby providing a new generation of forensic scientists with invaluable practical experience.

Students and educators at the graduate and undergraduate level colloquially report a lack of internship opportunities in the forensic anthropology laboratory. The fear of compromising the probative value of evidence and irregular and unpredictable caseloads are the most typically cited arguments against internship programs. These fears are not supported by documented courtroom challenges to admissibility and the practice of limiting participation presents a problem for a field that demands experience in order to progress professionally. A thoughtfully designed internship program may provide practical experience without necessitating a predictable caseload and without compromising evidentiary integrity.

The Metropolitan State University of Denver Human Identification Laboratory (MSUD-HIL) offers forensic anthropological search, recovery, and analysis services to medicolegal professionals throughout Colorado. Colorado's complex geography and the changes to biological evidence that occur in these diverse ecozones present challenging educational prospects for search and recovery as well as laboratory analyses not afforded by most classroom settings. In an effort to more effectively process vast outdoor scenes and provide students with the practical laboratory experience necessary for professional development, credited internships are offered to undergraduate students who have demonstrated exceptional academic performance and an interest in pursuing a career in forensic science. The model at MSU Denver utilizes a rigorous Student Quality Assurance (SQA) program in combination with direct supervision of student activities. It offers an alternative whereby budding professionals can gain the practical experience necessary to be successful while maintaining the probative value of evidence and enhancing the investigation.

Introducing an educational platform to scene processing may be beneficial to all involved, but presents a unique set of challenges necessitating foresight, planning, and a strict Quality Assurance (QA) program with the ultimate goal of maximizing the information recovered while maintaining the probative value of evidence. The MSUD-HIL program utilizes a multipronged training and competency testing system specifically designed for student participation, which operates under the laboratory's primary QA protocols. The SQA is hierarchical in nature and devised of a series of benchmarks attained by the successful completion of internal and external training and testing. The level of student participation both in the field and in laboratory analysis is dictated by the certification level achieved. Certification levels are represented by a color-coded system so that qualified (and more importantly, unqualified) students may be readily identified in the field or laboratory, allowing supervisors to easily manage students and rapidly delegate tasks to appropriately qualified individuals.

The simple use of prominently displayed color-coded identification cards has demonstrated the added benefits of self-management and proactive training by student interns. Additionally, students tend to strive to attain higher qualifications with the assistance of more highly certified interns. This affords training experience to more skillful interns while reducing the burden placed on the laboratory director, engenders an ethos of active ongoing education, and demonstrates the importance of QA in the forensic laboratory. SQA is maintained through a series of standardized tests independently assessed by two members of laboratory management at each stage of certification. This ensures that standards are maintained while fostering a multidisciplinary, multi-perspective teaching environment. SQA in the MSUD-HIL required systematic and step-by-step processes, including development of the SQA framework within the primary QA framework, certification manuals, training and commitment among laboratory staff, internal assessment, and integration of SQA programs into the laboratory's annual action plans. Once these controls are in place, students make valuable contributions to any laboratory while reaping the benefits of practical experience. Medicolegal agencies retain the right to deny student participation, but the MSUD-HIL has had few cases where this right has been invoked. Most medicolegal agencies involved with cases where student participation was allowed have praised the students and the laboratory for professional conduct and frequent successful results. Thus, student participation with a rigorous SQA program in place can increase success rates and benefit all agencies involved.

Student Interns, Quality Assurance, Forensic Laboratory

A117 Not All Degree Days are Equal in the Rate of Decomposition: The Effect of Season of Death on the Relationship Between Gross Postmortem Decomposition and Accumulated Degree Days

Lennon N. Bates, MA, Arkansas State Crime Laboratory, 3 Natural Resources Drive, Little Rock, AR 72205; and Daniel J. Wescott, PhD, Texas State University, Dept of Anthropology, 601 University Drive, San Marcos, TX 78666-4684*

After attending this presentation, attendees will better understand the seasonal variation associated with Accumulated Degree Days (ADD) calculations for estimating time since death using gross morphological changes of human remains.

This presentation will impact the forensic science community by demonstrating that seasonal adjustments are needed when estimating time since death from the gross morphological characteristics of human remains in medicolegal death investigations.

The estimation of time since death is an important component of many medicolegal death investigations. Forensic anthropologists commonly calculate the number of ADD necessary to reach the gross morphological changes or stage of decomposition observed on the body.[1] The ADD is then used to estimate the time since death by working backward from the date of discovery until the past date when the calculated degree days are attained; however, seasonal variation in insect activity, humidity, solar radiation, and other factors may affect the ADD necessary to reach different stages of decomposition based on the season of death.[1,2] The purpose of this study was to investigate if there is seasonal variation in the ADD at different stages of decomposition for bodies discovered in an outdoor settings.

Seventy-five individuals donated to the Forensic Anthropology Center at Texas State (FACTS) between 2011 and 2013 were monitored during the decomposition period, and the day each body transitioned from fresh, early decomposition, advanced decomposition, and mummification was recorded.[2,3] The ADD necessary to reach each stage of decomposition was then calculated using local minimum and maximum ambient temperature data. An ADD of zero was recorded if the calculated degrees for a day were negative.[1] Two comparisons were then performed. First, the ADD required to reach each stage of decomposition were compared for bodies placed during traditional seasons: winter (December-February), spring (March-May), summer (June-August), and fall (September-November). Second, the bodies were split into four temperature season categories based on average daily temperature for the month: Temperature Period (TP) 1 — 10°C-15°C (December, January, February); TP2 — 15.5°C-20.5°C (March, April, November); TP3 — 21°C 26°C (May, September, October); and TP4 — 26.5°C-30.5°C (June, July, August). The ADD necessary for each of the following decomposition periods were examined: (1) placement to early decomposition; (2) placement to advanced decomposition; (3) placement to mummification; (4) early to advanced decomposition; and, (5) advanced decomposition to mummification. *T*-tests were used to examine the hypothesis of no seasonal or temperature season variation in ADD required to reach each stage of decomposition.

The results indicate similar decomposition rates for the fall and winter and for the spring and summer. Therefore, the bodies were lumped into two broad seasonal categories: fall/winter and spring/summer. There were statistically significant differences in ADD required for each decomposition period for bodies placed in the fall/winter compared to those placed in the spring/summer. On average, in the fall/winter, 147 ADD were necessary to reach early decomposition, 342 were needed to reach advanced decomposition, and 798 ADD were required from placement to mummification. For the bodies placed in the spring/summer, 76 ADD were needed to reach early decomposition, 209 for advanced, and 512 ADD for mummification. When the bodies were divided based on average monthly temperature, a similar pattern was observed, except for ADD required to reach mummification after placement. There was a negative relationship between average temperature category and ADD required to reach early and advanced decomposition; however, fewer ADD were required to reach mummification in the TP3 (May, September, October) compared to all others. From placement to mummification required 792 ADD in TP1, 737 in TP2, 492 in TP3, and 529 in TP4.

This study demonstrates that it is necessary to control for season of death when using ADD and gross morphological stages of decomposition to estimate season of death. Traditionally, ADD is used in the estimation of time since death rather than calendar days because ADD provides a measure of the thermal energy units available for decomposition and is supposed to take into account temperature differences due to seasonal variation. The results of this study demonstrate that individuals that die during the fall/winter require more ADD than those that die during the spring/summer for all decomposition periods. While temperature is an important factor in postmortem decomposition, seasonal variation in insect activity and other abiotic environmental conditions (e.g., humidity, solar radiation, time below and above thresholds) cause more rapid decomposition that requires less ADD in warmer months compared to colder months in Central Texas.

A118 A Comparison of Seasonal Decomposition Patterns Between Human and Non-Human Animal Models

Angela M. Dautartas, MA, University of Tennessee, 250 S Stadium Hall, Knoxville, TN 37996; Dawnie W. Steadman, PhD, University of Tennessee, Dept of Anthropology, 250 S Stadium Hall, Knoxville, TN 37996; Amy Z. Mundorff, PhD, University of Tennessee, Dept of Anthropology, 250 S Stadium Hall, Knoxville, TN 37996; Lee Meadows Jantz, PhD, University of Tennessee, Dept of Anthropology, 250 S Stadium Hall, Knoxville, TN 37996-0720; and Giovanna M. Vidoli, PhD, University of Tennessee, Dept of Anthropology, Knoxville, TN 37996*

After attending this presentation, attendees will understand the difference in seasonal patterns of decomposition between humans and two frequently used animal proxies: pigs and rabbits. Attendees will further understand the challenges of applying a commonly used decomposition scoring system to animal remains.

This presentation will impact the forensic science community by discussing whether two species of animal proxies are adequate substitutes for human cadavers for decomposition studies in forensic contexts.

Animal remains are utilized in postmortem interval studies if human subjects are unavailable. It is undetermined if these animal models will yield data that are directly comparable to human patterns, as systematic research comparing decomposition variables between subject species is scarce in the forensic literature. This presentation continues the discussion from the 2015 American Academy of Forensic Sciences (AAFS) Annual Scientific Meeting of a two-year multidisciplinary validation study that compared three cadaver species during three trials that differed by season and microenvironment at the University of Tennessee's Anthropology Research Facility (ARF). The specific purpose of this presentation is to present the results of the analysis of the morphological decomposition rates of all three species across all three trials and seasons; the previous paper detailed only the results of the spring trial.

During each of three trials, five subjects of each species were placed in the same microenvironment at the ARF. Each trial took place during three different seasons (spring, summer, and winter) and in three different microenvironments within the ARF. Decomposition stage was recorded twice daily by applying the Total Body Score (TBS) system of Megyesi et al.[1] Daily photographs were also collected and temperature data was captured hourly.

The TBS scores of all three trials were analyzed using fuzzy clustering. This method was selected because it allows for incorporation and direct comparison of the data from all three seasonal trials. Unlike other clustering methods, the algorithm in fuzzy clustering allows for overlap between group memberships. This is important in this scenario when the question is how much commonality can be found between the patterns of decomposition of the three subject species. The species were compared on the basis of their TBS for specific Accumulated Degree Days (ADD) and also marked by season. If the animal models are a sufficient proxy for human remains, then the animal subjects should show a TBS similar to the humans at the same number of ADD. This would then lead them to be assigned to the same group or cluster.

When all three species were analyzed together, the pigs and humans consistently grouped together in one cluster, while the majority of the rabbits formed their own group. This reflects that the decomposition pattern between pigs and humans is much more comparable than either species is to rabbits. When the rabbits were removed from the analysis to compare only the pigs and the humans, the pigs formed the main cluster, with some of the humans included with the pigs and some humans in a separate group. This reflects the high amount of variability seen in the human specimens as opposed to the consistency across species observed in the pigs.

One of the challenges in this study was applying the TBS system to the animal models. Multiple stages listed in the TBS system rely upon visual cues of decomposition. While indicators such as color changes, skin slippage, and bloat were easily visible on the pigs, the thick fur and small body size of the rabbits often obscured these indicators, making it more difficult to determine stage of decomposition of the rabbits. Use of consistent methods of evaluation is needed in order for research data to be comparable to other studies and must be accurately applied to all specimens.

This project was supported by the National Institute of Justice, Office of Investigative and Forensic Sciences, United States Department of Justice. The opinions, findings, and conclusions or recommendations expressed in this presentation are those of the researchers and do not necessarily reflect the views of the Department of Justice.

Forensic Anthropology, Decomposition, Taphonomy

A119 Around the World in Accumulated Degree Days

Tal Simmons, PhD, Virginia Commonwealth University, Dept of Forensic Science, 1015 Floyd Avenue, Richmond, VA 23284; Colin Moffatt, PhD, UCLAN, School of Forensic & Inv Sci, Preston, Lancashire PR1 2HE, UNITED KINGDOM; Ozgur Bulut, PhD, Hitit University, Facutlty of Arts & Sciences, Department of Anthropology, Corum, TURKEY; Natnipoon Rattanarungruang, BA, 67 Soi Ngamwongwan 21, Bang-khen, Muang Nonthaburi, Nonthaburi, THAILAND; Amanda L. Roe, PhD, College of Saint Mary, 7000 Mercy Road, Omaha, NE 68106; and Donald F. Siwek, PhD, Dept Anatomy and Neurobiology, Program in Forensic Anthropology, 72 E Concord Street, Boston, MA 02118*

After attending this presentation, attendees will better understand how the relationship between Accumulated Degree Days (ADD) and Total Body Score (TBS) can be used to compare and contrast the rate of decomposition across geographic regions around the world.

This presentation will impact the forensic science community by providing results from a controlled experiment conducted simultaneously in five locations in four countries. This presentation will broaden the understanding of how temperature and insects drive the decomposition process, while exploring the effect of local climate and ecosystems.

The vast majority of previously published studies, using either human cadavers or animals, explored specific variables and how these affected the decomposition process; these investigated the effects of individual variables within a single site, with no comparison across different sites. This experiment investigated surface decomposition in five localities in four countries. Research sites included Nakhon Nayok province, Thailand; Ankara, Turkey; Lancashire, England; and Massachusetts and Nebraska in the United States. Average daily temperatures, climatic and geographic conditions, and insect communities varied widely among these sites.

The experiment was initiated in all five localities during the first week of June 2014. Each facility used ten pigs and, with the exception of the Turkish site where pigs were killed by lethal injection, all animals were killed with a captive bolt within one to two hours of being placed at the site. The agreed protocols specified that the pigs should be in the weight range 20kg-40kg in order to minimize body mass differences, as these are known to affect the rate of decomposition.[1] Unfortunately, several sites deviated. Neither Massachusetts nor Nebraska could comply with scavenger proofing and scavenging was observed to some extent at both sites; Nebraska and Thailand clustered at the low end of the specified weight range (21kg and 25kg average weight, respectively), while the other three exceeded the high end (England=43kg; Massachusetts=45kg; Turkey=51kg). As a result of these differences, it is important to note that the data are quite sensitive to the statistical method used and how weight is dealt with within the statistical model.

At all sites, pigs were monitored and observations were recorded approximately every 50 ADD. Observers recorded TBS as well as insect diversity and activity. The pigs were also photographed and scores cross-checked for inter-observer error and internal consistency. Insect taxa were identified by local entomologists working with the observers.

A mixed-effects linear model with TBS as the response variable was used, which took into account the effect of weight as a random variable. The maximum likelihood method was used to produce estimates and their errors. The effects of log10ADD ($F_{1,1086}=18400$, $p<0.0001$) and location ($F_{4,1086}=90.6$, $p<0.0001$) were both significant as was the interaction between log10ADD and location ($F_{4,1086}=224$, $p<0.0001$). The rate of decomposition at different locations was as follows: Nebraska and Massachusetts were similar in rate ($t=1.90$, $df=1087$, $p=0.058$), but different to all others ($t>4.5$, $df=1087$, $p<0.0001$). England was also similar to Massachusetts ($t=1.82$, $df=1087$, $p=0.07$), but different to all others ($t>4.5$, $df=1087$, $p<0.0001$). Turkey and Thailand are also similar ($t=1.61$, $df=1087$, $p=0.11$), but different to all others ($t>13.5$, $df=1087$, $p<0.0001$). The hierarchy in rate was Nebraska > Massachusetts > England >> Thailand > Turkey.

There is much to be considered based on these data, including whether: (1) the rate at which temperature is accrued temperatures (e.g., Massachusetts and Nebraska) affects decomposition rate more than simply the sum of temperatures; (2) the role of fluctuating temperatures affected ADD and insect development; (3) the role of scavenging impacted the unprotected sites; (4) differences in insect communities accounted for varied decomposition rates; and, (5) drug residues in the Turkish animals accounted for slower decomposition.

Taphonomy, Accumulated Degree Days, Decomposition

A120 Comparing Decomposition Assessments From Digital Images to In Situ Observations

Gretchen R. Dabbs, PhD, Southern Illinois University, Dept of Anthropology, 1000 Faner Drive, MC 4502, Carbondale, IL 62901; Joan A. Bytheway, PhD, Sam Houston State University, College of Criminal Justice, Box 2296, Huntsville, TX 77341-2296; and Melissa A. Connor, PhD, Colorado Mesa University, 406 Lowell Heiny Hall, 1100 N Avenue, Grand Junction, CO 81501-3122*

After attending this presentation, attendees will learn that the final assessment of the degree of decomposition of a human corpse is not significantly different when the observations of the degree of decomposition are made from digital images of the body taken *in situ* versus when the observations are made directly against the body *in situ*.

This presentation will impact the forensic science community by demonstrating that observation of human decomposition from digital images is a sufficient, and sometimes necessary, method for assessing human decomposition and that the degree of decomposition observed in digital images is not statistically different than that observed on the corpse *in situ*.

In the course of normal events in forensic anthropology, it occasionally becomes necessary to make assessments of the level of human decomposition based on the observation of digital images, instead of the corpse *in situ*. Whether this be for consultation with law enforcement after the deceased has been interred, or for empirical data collection protocols, the question of the degree of agreement between assessments made using these two distinct methods has not yet been addressed in forensic anthropology.

Sixteen participants scored 59 observation packets including digital images using the Total Body Score (TBS) system originally described by Megyesi et al.[1] The participants included both sexes and ranged in education (undergraduate to PhD) and experience (<six months to ten+ years). The packets used 13 human cadavers in different stages of decomposition (Postmortem Interval (PMI) 2 days-186 days) from three outdoor human decomposition research facilities. All observers were recruited for this study from existing human decomposition research facilities and had at least some experience using the TBS method for quantifying decomposition. Observers were provided the scoring tables from Megyesi et al.'s publication and instructed to follow only those descriptions, disregarding any modifications in use by individual facilities and to return categorical scores for each bodily area (head/neck, trunk, and limbs), as well as overall TBS scores. When decomposition fit into more than one category or spanned multiple categories, observers recorded both categories and averaged the contribution to TBS, as instructed by the original publication. Data were collated and the TBS recorded by the project participant was compared to the TBS recorded by the on-site observer at the decomposition research facility the subject was donated to using paired-samples *t*-tests with Bonferroni correction (α=0.003125) (Statistical Package for the Social Sciences (SPSS) v. 22.0).

The average absolute difference in TBS between the on-site and digital image observations ranged from 0.03 to 2.28, with 12 of 16 observers having an average difference in TBS of less than one point. Of the 16 comparisons made, only two cases (12.5% of total sample) demonstrated statistically significant differences between the TBS score recorded by the on-site observer and that recorded by the project participant based on observation of digital images ($p \leq 0.001$). In both cases, the observer of the digital images was an undergraduate student with less than one year of experience assessing decomposition using the Total Body Score method.

Given these findings, it is suggested that observations of human decomposition based on digital images can be substituted for observations based on actual observation of the corpse *in situ* when necessary, as there is generally good agreement between the evaluation of the degree of decomposition using both methods. The one caveat to this statement is that when the observer has little experience (i.e., less than one year), it is best to make this substitution with caution.

This study was conducted with the approval of the Southern Illinois University Human Subjects Review Committee.

Forensic Anthropology, Data Validation, Digital Images

A121 Volatile Organic Sulphur Compounds (VOSCs) and Accumulated Degree Days (ADD): Timing the Switch From Anaerobic to Aerobic Putrefaction

Philip E. Houldsworth, MSc, 19 Gynn Avenue, Blackpool, Lancashire FY1 2LD, UNITED KINGDOM; and Tal Simmons, PhD, Virginia Commonwealth University, Dept of Forensic Science, 1015 Floyd Avenue, Richmond, VA 23284*

After attending this presentation, attendees will better understand: (1) the link between VOSCs generated during decomposition and the timing of the switch between anaerobic and aerobic putrefaction; and, (2) how the processes involved in the timing of this switch may increase understanding in the hunt for the elusive Postmortem Interval (PMI).

This presentation will impact the forensic science community by providing data on the VOSCs generated by the putrefactive processes as they progress in individual tissues types. The findings contribute to forensic taphonomic research by improving understanding of the chemical and microbial processes that take place immediately after death and assisting in the goal of improved PMI estimation.

Previously, the research in this area was carried out on whole human cadavers and/or animals. The Volatile Organic Compounds (VOC) were collected by concentrating them from the air above cadavers, which produced large numbers of VOC in very complex patterns.[1,2] The goal of this research was to examine the putrefaction processes in individual tissue types and to analyze the VOC in a controlled laboratory environment in order to simplify the pattern and reduce the number VOC produced within a given time frame. By both reducing and controlling the variables investigated, a better interpretation of the VOC and VOSC production processes and their relationship to Accumulated Degree Days (ADD) is possible.

The research was conducted using tissues (liver, heart muscle, and skeletal muscle) harvested from a freshly killed pig (*Sus scrofa domestica*). Tissues were immediately placed on ice to slow the onset of autolysis. Porcine fecal material was used as a source of enteric bacteria to initiate the putrefactive process. Five grams of tissue were placed into a series of triplicate headspace vials, and 0.5ml of fecal materials was added to the tubes. Along with controls consisting of tissue blanks, air blanks, and fecal material blanks, the sealed vials were placed in a hot air incubator at 37°C for five days to initiate putrefaction. The temperature was monitored and recorded throughout the experiment, so that the amount of VOC produced could be related to the ADD at each sampling point. The VOC in the headspace above the tissue was extracted, separated, and identified by the Headspace/Gas Chromatograph/Mass Spectrograph (HS/GC/MS) at 24-hour intervals for eight days.

The most significant VOC produced during the eight days of data collection were the VOSCs Methyl Mercaptan (MM), Dimethyl Sulphide (DMS), Dimethyl Disulphide (DMDS), and Dimethyl Trisulphide (DMTS). Statistical analysis shows that there is a strong relationship between the production of VOSC and ADD in different tissue types. In liver tissue, the amount of DMDS and DMTS generated was very strongly related to ADD ($p < 0.005$) above 280 ADD. In heart tissue, DMDS was very strongly related to ADD ($p < 0.005$) above 280 ADD, whereas in skeletal muscle, only MM was very strongly related to ADD ($p < 0.005$) above 310 ADD. As DMDS and DMTS are produced by the oxidation of MM and as MM is produced by an anaerobic process, the relationship of these compounds to one another can indicate the presence of anaerobic or aerobic conditions and the switching from one condition to another over time.

In conclusion, the order of decomposition evinced by the results of this study (liver > heart > skeletal muscle) is the same as that described by Gill-King.[3] The switching between anaerobic and aerobic conditions as indicated by the relationship between VOSC and ADD has not been demonstrated previously, and further research is required to establish the determining factors.

Decomposition, Acumulated Degree Days, Volatile Organic Compounds

A122 An External Validation of the Citrate Content Postmortem Interval (PMI) Method

Michael A. Brown, PhD, College at Brockport, SUNY, Dept of Chemistry and Biochemistry, Brockport, NY 14420; Charles Froome, BS, College at Brockport, SUNY, Dept of Chemistry, Brockport, NY 14103; Shawn Hennessy, College at Brockport, SUNY, Dept of Chemistry, Brockport, NY 14420; Rebecca Gerling, College at Brockport, SUNY, Dept of Chemistry, Brockport, NY 14193; Jeffrey Ellison, BS, College at Brockport, SUNY, Dept of Chemistry, Brockport, NY 14420; and Ann W. Bunch, PhD, SUNY Brockport, Dept of Criminal Justice, 160 Albert Brown Bldg, Brockport, NY 14420*

The goal of this presentation is to provide an update on the external validation of Schwarcz et al.'s method of measuring citrate content of bone to indicate PMI.

This presentation will impact the forensic science community by addressing the potential of Schwarcz et al.'s citrate content of bone method as a predictor of PMI. In addition, its use as an initial sorting tool for ancient versus more recent remains will be discussed.

The PMI of skeletonized remains is a crucial piece of information that can help establish the time dimension in criminal cases. Unfortunately, the accurate and reliable determination of PMI from bone continues to evade forensic investigators despite concerted efforts over past decades to use qualitative and quantitative methods. Qualitative methods have come under greater scrutiny, since the publication of the 2009 National Academy of Sciences Report, Strengthening Forensic Science in the United States – A Path Forward.[1] The numerous quantitative methods (e.g., luminol, radionuclide, carbon-14 bomb spike, and DNA) that have been developed lack the accuracy and/or precision required for reliable PMI estimation.[2-5]

A relatively new PMI method based on the analysis of citrate content of bone was developed by Schwarcz et al.[6] The researchers report that the citrate content of bone decreases with an increase in PMI and that the rate does not depend significantly on storage conditions.[6] Kanz et al. performed an external validation study of this method on cemetery-derived bones with PMIs ranging from ~27 years to 52 years.[7] Their results suggested that the "accuracy of PMI determination was unsatisfactorily low;" nevertheless, the method may show promise for classifying samples as recent or historic.[7] The main objective of this research was to also externally validate the citrate content PMI method and optimize where needed.

More than 50 samples from the University of Tennessee, Knoxville's Forensic Anthropological Research Center and the Onondaga County Medical Examiner's Office were analyzed in this research. The bone samples were prepared using the procedures utilized by Schwarcz et al. with slight modifications to improve method performance. The citrate content (wt%) of each bone sample was determined by an Ultraviolet/Visible spectrometry (UV/Vis) enzyme assay and by High-Performance Liquid Chromatography (HPLC).

Initial studies focused on the assessment of method accuracy, precision, detection limit, and spike recovery. The accuracy for both methods was within ±5 relative error and the precision was less than 2% relative standard deviation. The limit of quantification was ~0.017wt% citrate for both techniques, which is similar to the value reported by Kanz et al. The method reporting limit, which is a more realistic value for PMI determination, was found to be ~0.1wt% citrate for both techniques. A bone sample with a PMI of 173 years was analyzed in order to test the detection limit of the methods and resulted in a citrate value of 0.169 (±0.006) wt % for HPLC and just below the method reporting limit for the UV/Vis assay. Spike recoveries performed for all samples averaged in the range on 95% to 105%. Studies were also performed to establish a baseline citrate content in remains of recently deceased persons (PMI=2 years or less). The baseline was determined to be 1.21 (±0.03) wt% by HPLC and 1.19 (±0.04) wt% by UV/Vis assay. This value is statistically different than the value (2.0 (±0.1) wt%) stated by Schwarcz et al.; however, it is similar to theoretical and experimental values found in the literature.[8-10] Preliminary results from analyzing samples with PMI greater than two years suggest that the theoretical correlation between citrate content of bone and PMI is much weaker than reported by Schwarcz et al., although it is similar to the results of Kanz et al. Despite these findings, this method may still serve as a technique to sort ancient from more recent skeletal cases after further, similar validation studies have been conducted.

This project is funded by a National Institute of Justice Grant.

Postmortem Interval, Citrate, Skeletal Remains

A123 Differentiating Between Sharp Force Trauma (SFT) Defects and Insect Invasion of Skin of Human Cadavers Throughout the Decomposition Process

Joan A. Bytheway, PhD, Sam Houston State University, College of Criminal Justice, Box 2296, Huntsville, TX 77341-2296; Kevin R. Derr, 28601 Shawnee Court, 192 Waterwood, Huntsville, TX 77320; Zachary Lueck, BS, Sam Houston State University, 10700 Vista Heights Boulevard, Fort Worth, TX 76108; Lyndi S. Turner, BS, Sam Houston State University, 1235 Josey Street, Apt 171, Huntsville, TX 77340; Kandace D. Schakelford, BA, Sam Houston State University, 1742 CR 233, Tyler, TX 75705; Erica N. Fisher, BS, Sam Houston State University, 9318 Floral Crest Drive, Houston, TX 77083; and Luis Dominguez, BS, Sam Houston State University, Box 2296, Huntsville, TX 77341*

After attending this presentation, attendees will understand that SFT skin defects, induced by a variety of sharp instruments, can be recognizable and distinguished from insect invasion defects throughout the human decomposition process into the late phases of the advanced stage. Issues that affect the margins of SFT will also be addressed.

This presentation will impact the forensic science community by providing results of SFT to skin from a controlled but natural environment (simulating how bodies would appear if dumped outdoors and eventually found) study in which no current human taphonomic research exists. This presentation will acknowledge the need for collaboration of human decomposition studies with trauma studies on both hard and soft tissue. This study will also broaden the forensic taphonomy research arena.

SFT in bone and cartilage is well documented in forensic literature and recent literature documents SFT evidence on hair and fabric; however, there is no literature on the effects of taphonomy on SFT of the skin and whether it is identifiable and distinguishable from insect activity throughout the decomposition process.[1-11] In most cases, SFT is identifiable by the pathologist on bodies in the fresh stage of decomposition and observed with less certainty when the body is in an advanced stage of decomposition. It is not known whether particular sharp instruments that produce a certain pattern on the body in the fresh stage of decomposition will maintain that pattern in the late stage of decomposition. In addition, do sharp instruments produce a particular pattern when used in any area of the body and is the pattern visible throughout decomposition? If the patterns are recognizable, can they be distinguished from insect activity?

This study was conducted at the Southeast Texas Applied Forensic Science (STAFS) facility at Sam Houston State University. The climate of southeast Texas is humid and subtropical with a latitude of 30°N, resulting in high heat indices that produce early desiccation in cadaver tissue.[12]

SFT defects of the human skin, how those changed throughout the course of decomposition, and how they were distinguished from insect defects was examined. Eight sharp instruments were used to induce SFT on four human subjects at eight areas of the body: the right and left sides of the neck, right and left abdomen, right and left thigh, and the antero-medial area of the right and left lower leg. Each subject was in a fresh stage of decomposition, unclothed, and in a supine position at the time of the SFT induction. Subjects were protected from scavenging by wire cages. Bodies were accessible to the outdoor environment, including insects. Inflictions at the neck were at an angled, downward motion while those at the abdomen, thigh, and lower leg were downward motions. Instruments used included a Ryobi® reciprocating saw, a Marshalltown® trowel, an Estwing® axe, a Condor® Crocodilian machete, an HDX® clawed hammer, a Dexter Russell® knife, an Ace® shovel, and an HDX® screwdriver.

Length and width measurements were taken of each wound in the fresh stage (Day 1) of decomposition and again 27 days later in the advanced stage. As expected, SFT wounds increased in length and width as decomposition progressed. In some cases, SFT defect edges near the ground tended to mix with decomposition fluid, resulting in a "melted" appearance of the skin, and SFT margins were no longer clearly recognizable for measuring. For SFT measurements that could be taken at both the fresh and advanced stages for each instrument, percentage length increase ranged from 2% to 83%, with the clawed hammer having the largest average percentage length increase (57%). Percentage width increase ranged from 14% to 88%, with the axe having the largest average percentage width increase (76%). All SFT wounds were still evident into the advanced stage of decomposition and were distinct from insect activity defects. Insect defects were predominantly circular in appearance and measured 1mm to 4mm in diameter. Insect defects were located adjacent to SFT defects and consisted of multiple small circular holes clustered together. The holes were also found in areas with thinner skin tissue, such as the shin. The groin areas of all four subjects (where no SFT was created) showed large openings with indistinguishable skin margins dissimilar to SFT openings. The natural orifices of the groin enabled insects to more easily invade and create skin defects that were not observed on other areas of the body.

Human Decomposition, Sharp Force Trauma, Taphonomy

A124 The "Science of Science": Examining Bias in Forensic Anthropology

Alexandra R. Klales, PhD, Mercyhurst University, Dept of Applied Forensic Sciences, 501 E 38th Street, Erie, PA 16546; and Kate M. Lesciotto, JD, MS, 227 Oakwood Avenue, State College, PA 16803*

After attending this presentation, attendees will understand one form of bias that impacts the interpretation of human remains in forensic anthropological contexts and will better understand how bias impacts the decision-making process. This presentation will further attendees' abilities to join the conversation on how best to incorporate objectivity into the application of forensic anthropological methods.

This presentation will impact the forensic science community by detailing an area of bias that has not yet been studied within forensic anthropology and by engendering a discussion of bias, which is needed to understand how to best move forward with hypothesis-driven research, specifically for generating the biological profile of unidentified human remains.

Since *Daubert*, there has been a push within the anthropology discipline to rely more heavily on objective methods.[1] Recently, the subject of bias when estimating biological profile parameters through non-metric methods has begun to be addressed in relation to objectivity.[2,3] Bias can be introduced into forensic investigations in many ways. The role of forensic anthropologists and scientists is to remain objective; however, recent studies have shown that cognitive bias does impact the interpretation of human remains, as well as the final conclusions drawn, when additional contextual information is provided.[2,3]

The observers' conclusion when assessing biological profile parameters can often "result from expectations about the results of an observation, and such expectations often come either from explicit messages or from subtle cues about the thing to be observed."[4] The goal of this research is to examine the latter, known as the gestalt — that is, the overall impression of the remains when examining individual non-metric traits. To accomplish this, seven experienced observers blindly scored Phenice's three non-metric traits (ventral arc, subpubic contour, and medial aspect of the ischio-pubic ramus) from one (female) to five (male) based on the descriptions and figures from the Klales et al. method for sex estimation.[5,6] To limit the potential influence of contextual bias, participants were informed that they were participating in an observer error study, rather than a bias study. Each trait was scored on a separate day. The 15 innominates were randomly arranged with all identifying markers obscured. Only the specific trait being scored was visible; the remainder of the bone was covered to prevent observation of other traits or robusticity of the bone from influencing the scoring process. On the final day, observers were asked to provide an overall impression of sex and score each trait again, but this time they were allowed to examine the entirety of the bone and all traits simultaneously.

The results indicate a strong confirmation bias, whereby "if one has expectations about an event, or hypothesis (i.e., sex estimation)…one tends to draw selectively from the available evidence and focus on those items that confirm the working hypothesis."[4] When the observer was able to view the entire innominate, including all traits and general size/robusticity, every single observer (100%) feminized or masculinized individual trait scores according to their sex assessment. For example, if the observer originally scored the subpubic contour as 2 (slight concavity), they tended to feminize the score to 1 (well-developed concavity) when they viewed the other traits and estimated the innominate to be female. In the original Phenice article, presence of all three traits was considered to be the female form.[5] Therefore, it is not necessarily surprising that the female innominates were feminized to a greater degree, especially for the subpubic concavity (100% of specimens were feminized by at least one score by observers). The ventral arc was also heavily feminized (83%), while the medial aspect was more consistent: only 33% of females were feminized and only 44% of males were masculinized. Previous research has shown high observer agreement for each of these traits, which further suggests that bias is more likely the cause of within-individual scoring discrepancies.[6]

Bias from contextual information has been previously identified and, with this research, bias from the gestalt has also been confirmed.[2,3] Research and methodology in forensic anthropology must remain hypothesis-driven and objective; the next step in the discipline is to begin a discussion of how best to go about accomplishing this task, given the biases known to be present so that we may better understand the science of our science.

Bias, Non-Metric Traits, Biological Profile

A125 A Reanalysis of Korean War Anthropological Records to Support the Resolution of Cold Cases

Emily K. Wilson, Defense POW/MIA Accounting Agency, 310 Worchester Avenue, Joint Base Pearl Harbor-Hickam, HI 96815*

After attending this presentation, attendees will be informed concerning the accuracy of 1950s Korean War identification data used to develop certain reference methods.

This presentation will impact the forensic science community by expanding awareness of the complications affecting age at death and stature estimation using 1950s reference methods.

The Defense POW/MIA Accounting Agency Central Identification Laboratory (CIL) has developed a disinterment project to prioritize exhumations of unidentified remains from the Korean War for laboratory analysis and identification. These cases were previously processed at the Central Identification Unit (CIU) in Kokura, Japan, and were buried as unknown. Since 1999, the CIL has disinterred 94 sets of Korean War remains and identified 55 individuals. This process has made available for comparison from each of these 55 cases: (1) the original CIU anthropological assessments; (2) blind CIL assessments made for those same remains; and, (3) the reported antemortem information from each individual identified at the CIL. Zinni presented preliminary comparisons for a portion of these cases.[1] This study presents a comparison of the biological estimations for age at death, stature, and ancestry at both the CIU and the CIL with the reported antemortem information. The purpose of this study is to find patterns of errors that are useful in refining disinterment research (in which more accurate biological profiles are extrapolated from CIU notes prior to exhumation) and in supporting current identification efforts.

The CIU age ranges captured the reported age at death in 58.5% of cases and did not in 41.5% of cases. When the age was overestimated, the reported age was an average of 1.6 years younger than the lower limit of the CIU range (min. 0.25 years; max. 4 years). When the age was underestimated, the reported age was an average of 2.1 years older than the upper limit (min. 0.5 years; max. 4.75 years). CIL age ranges captured the reported age at death in 90.6% (48/53) of cases and did not in 9.4% (5/53) of cases. All five cases for which the CIL range did not capture the reported age at death resulted from underestimation. All five underestimations at the CIL were also underestimations at the CIU. In three of those five underestimations, CIL analysts had exclusively used McKern and Stewart (a method developed from the 1950s Korean War identifications) as a reference.[2]

Reported stature was captured by modified CIU age ranges in 79.2% (42/53) of cases and was not captured in 20.8% (11/23) of cases. When the stature was not captured, 54.5% (6/11) were overestimated and 45.5% (5/11) were underestimated. When the stature was overestimated, the reported stature was an average of 0.9 inches under the CIU estimate (min. 0.1 inches; max. 2.5 inches). When the stature was underestimated, the reported stature was an average of 0.8 inches over the CIU estimate (min. 0.25 inches; max. 1.5 inches). The CIL captured the reported stature in 88.7% (47/53) of cases. When the stature was not captured, 50% (3/6) were overestimated and 50% (3/6) were underestimated. All six cases in which the CIL estimation did not capture the reported stature were also cases in which the CIU did not capture the reported stature, and each in the same direction (over- or underestimated). Trotter and Gleser formed the basis of both the CIU and CIL estimations.[3]

The CIU captured the reported race in 96.2% (51/53) of cases and did not in 3.8% (2/53) of cases. The CIL captured the reported race in 100% (53/53) of cases. Fewer errors are made today at the CIL, but they are the same types of errors. Understanding these systematic errors in 1950s CIU-developed reference data is useful for refining disinterment research and supporting current identification efforts.

Cold Case, Age-At-Death, Stature

A126 The Status of Unidentified Decedent Cold Cases at the Harris County Institute of Forensic Sciences (HCIFS) From 1957 to 2015

Cate E. Bird, PhD, Pima County Office of the Medical Examiner, 2825 E District Street, Tucson, AZ 85714; Sharon M. Derrick, PhD, Harris County Institute of Forensic Sciences, 1885 Old Spanish Trail, Houston, TX 77054; Deborrah C. Pinto, PhD, Harris County Institute of Forensic Science, 1885 Old Spanish Trail, Houston, TX 77054; Jason M. Wiersema, PhD, Harris County Institute of Forensic Science, 1885 Old Spanish Trail, Houston, TX 77054; and Jennifer C. Love, PhD, OCME, 401 E Street, SW, Washington, DC 20024*

After attending this presentation, attendees will have a better understanding of how forensic anthropologists have significantly contributed to identifying unknown decedents at the HCIFS.

This presentation will impact the forensic science community by reviewing overall patterns of unidentified cold cases, highlighting the challenges of medicolegal identifications, and summarizing the role forensic anthropologists have played in successfully identifying decedents in the medical examiner setting.

The Forensic Anthropology Division (FAD) at HCIFS has actively pursued the identification of unknown decedents in the greater Houston area since 2006. Currently, the FAD maintains records on approximately 340 provenienced unidentified human remains dating from 1957 to 2015. The majority of the decedents are from the 1980s (35%) and the 1990s (29%), with the number of unidentified cases decreasing steadily to the present. Approximately 78% of the decedents are male and 21% are female, with Whites (37%) and Hispanics (29%) being the most common ancestral groups represented. The manner of death in the majority of the cold cases is either undetermined (43%) or homicide (32%). While 40% of the unidentified decedents have fingerprints available, only 27% of the cases have faces appropriate to disseminate to the public. One of the primary problems with identification of unknown decedents is body condition at discovery. More than two-thirds of the HCIFS cold case remains were decomposing or skeletal at autopsy, which hinders identification because many individualizing characteristics (e.g., facial recognition, fingerprints, etc.) are lost when soft tissue features disappear. A further complication of identification efforts is that even when decedents were not decomposing, traumatic injuries often precluded the possibility of visual identification. In order to increase the likelihood of identifications, the FAD publishes other recognizable attributes of decedents, such as tattoos, personal effects, jewelry, clothing, distinctive fingernails, or dental restorations.

Forensic anthropologists have played a key role in recognizing, organizing, and publicizing unidentified decedent cold cases at HCIFS. Primary responsibilities undertaken by the FAD include reviewing all available records, resubmitting fingerprints to appropriate databases, updating decedent profiles (e.g., National Missing and Unidentified Persons System (NamUs), National Crime Information Center (NCIC), and National Center for Missing and Exploited Children (NCMEC)), performing anthropological analyses, and collecting DNA for analysis and upload to Combined DNA Index System (CODIS). Over the past 10 years, the FAD has received two National Institute of Justice (NIJ) grants, funded two postdoctoral forensic anthropology Fellows, and exhumed the remains of 46 unidentified decedents for the purposes of identification. Due to the concerted efforts of forensic anthropologists at HCIFS, approximately 54% of the unidentified decedent cold cases have DNA submitted or uploaded to CODIS, and all available fingerprint cards have been digitized and resubmitted to appropriate agencies within the past four years. Also, in the last decade, 84 decedents whose cases date back to 1971 have been identified, primarily through fingerprint resubmissions (51%) or DNA matches (36%).

This presentation highlights the demographic trends among the unidentified cold case decedents from Harris County and surrounding areas during the last 50 years. It also illustrates challenges encountered during this endeavor and the significant role forensic anthropologists can play in organizing and resolving unidentified decedent cases in a medicolegal setting.

Unidentified Decedents, Personal Identification, Cold Cases

A127 The ANSI-ASQ National Accreditation Board (ANAB) Accreditation of the Harris County Institute of Forensic Sciences' Forensic Anthropology Division

Christian Crowder, PhD, Harris County Institute of Forensic Sciences, 1885 Old Spanish Trail, Houston, TX 77054; Michal L. Pierce, MS, Harris County Institute of Forensic Sciences, 1885 Old Spanish Trail, Houston, TX 77054; and Luis A. Sanchez, MD, Harris County Institute of Forensic Sciences, 1885 Old Spanish Trail, Houston, TX 77054*

After attending this presentation, attendees will: (1) understand the choices available for forensic agency accreditation and the differences between International Organization for Standardization (ISO) 17025 and ISO 17020; and, (2) learn the challenges faced by professionals practicing forensic anthropology when striving to have their facilities, procedures, and casework meet ISO 17020 standards.

This presentation will impact the forensic science community by discussing the importance of incorporating quality assurance programs and personnel into departmental operations and introducing forensic anthropology laboratory accreditation under the ISO/International Electrotechnical Commission (IEC) 17020 standard.

Following the publication of the 2009 National Academy of Sciences Report, *Strengthening Forensic Science in the United States – A Path Forward*, establishing quality assurance programs and achieving accreditation has become a priority for forensic anthropology practitioners. Until recently, there has been a lack of interest for accreditation boards to develop a program that recognizes forensic anthropology as a named accreditation program. The avenue for accreditation for medicolegal operations is under the National Association of Medical Examiners' (NAME) Standards. While forensic anthropology is mentioned in these standards, it does not specifically provide standards for the practice. The Defense POW/MIA Accounting Agency (DPAA), formally known as the Joint POW/MIA Accounting Command-Central Identification Laboratory (JPAC-CIL), developed a quality assurance program that ultimately led to the laboratory's accreditation by the American Society of Crime Laboratory Directors/Laboratory Accreditation Board (ASCLD/LAB) in 2003, making them the first credentialed forensic skeletal identification laboratory. In 2008, the laboratory was re-accredited under the ASCLD/LAB-*International* Program in Crime Scene and Trace Evidence using the ISO 17025 Standard. It has been questioned if placing the discipline of Anthropology under a trace laboratory rubric is the most appropriate fit; however, until recently, there were no other options available.

There are currently two ISO standards being used by accrediting bodies to accredit forensic science agencies: (1) ISO/IEC 17025 General requirements for the competence of testing and calibration laboratories; and, (2) ISO/IEC 17020 Conformity assessment-requirements for the operation of various types of bodies performing inspection.

While ISO/IEC 17025 has been widely accepted by crime laboratories for more than a decade, ISO/IEC 17020 has recently gained popularity with crime scene investigation units. The difference between the two standards, and therefore the focus of the respective accreditation programs, is mainly that one addresses analytical instrumentation and data more heavily than the other. ISO/IEC 17025 is geared toward laboratories whose experts report results based on data generated by analytical equipment, while ISO/IEC 17020 recognizes an expert's professional judgment as the means for determining function and acceptability. The latter is more suitable for anthropological examinations.

In 2013, The Harris County Institute of Forensic Sciences (HCIFS) identified a path toward achieving accreditation for forensic anthropology. This path involved building a quality assurance program that followed the American National Standards Institute-American Society of Quality (ANSI-ASQ) ANAB ISO/IEC 17020 Forensic Inspection Agency Accreditation program. Although the ANAB program recognizes a forensic anthropologist as one who reaches conclusions based on functional testing and professional experience, the program also calls for standardization of the work process and examination report. A challenge in building this program internally was finding a way to introduce new training, validation, and record-keeping requirements to experienced staff, who have been using standard methods for several years, without diminishing their sense of professionalism.

In 2015, the HCIFS became the first credentialed forensic anthropology laboratory under this program. Successfully attaining accreditation was a direct result from the Forensic Anthropology Division working closely with the agency's Quality Management Division on a daily basis to build, implement, and maintain the quality assurance program. Using separate quality assurance personnel who do not perform casework and are knowledgeable in basic accreditation requirements is ideal when working toward accreditation. It is recommended that other agencies assign quality assurance staff to assist with implementing and monitoring new quality programs in order to ensure that the proper checks and balances are in place.

Considering the growing momentum of the recently formed Organization of Scientific Area Committees (OSAC) and the continued integration of anthropology in medical examiner/coroner offices, the importance of quality assurance for the anthropology program and surety measures directly related to casework should be emphasized in any agency that utilizes this type of service. The milestone reached by the HCIFS Forensic Anthropology Division will hopefully pave the way for other practitioners to obtain accreditation for their services.

Quality Assurance, Accreditation, Forensic Anthropology

A128 Differential Raccoon Scavenging Among Pig, Rabbit, and Human Subjects

Dawnie W. Steadman, PhD, University of Tennessee, Dept of Anthropology, 250 S Stadium Hall, Knoxville, TN 37996; Angela M. Dautartas, MA, University of Tennessee, 250 S Stadium Hall, Knoxville, TN 37996; Amy Z. Mundorff, PhD, University of Tennessee, Dept of Anthropology, 250 S Stadium Hall, Knoxville, TN 37996; Giovanna M. Vidoli, PhD, University of Tennessee, Dept of Anthropology, Knoxville, TN 37996; and Lee Meadows Jantz, PhD, University of Tennessee, Dept of Anthropology, 250 S Stadium Hall, Knoxville, TN 37996-0720*

After attending this presentation, attendees will understand the differences in postmortem scavenger activity between human subjects and two common animal proxies for human decomposition — pigs and rabbits. Attendees will further understand whether raccoon scavenging of human remains is accurately reflected in animal models of human decomposition.

This presentation will impact the forensic science community by demonstrating whether two species of animal models are sufficient substitutes for scavenger and decomposition studies of human cadavers in forensic contexts.

Animal remains are often utilized in forensic research of the postmortem interval when human subjects are unavailable; however, systematic research that directly compares decomposition variables between subject species is lacking in the forensic literature. As a result, no basis exists to determine whether studies based on animal remains are relevant to situations involving questions of the postmortem interval of human forensic cases. A two-year project at the Anthropology Research Facility (ARF) at the University of Tennessee compared three cadaver species — pigs, rabbits, and humans — across three trials that differ by microenvironment and season. Data collected included insect species and activity, scavenger activity, and temperature and morphological changes in the bodies. This presentation focuses on scavenging across all three trials and specifically examines whether raccoons prefer one species over others and the seasonality of scavenger activity.

The project consisted of three trials in which five subjects of each species — pig, rabbit, and human — were placed across three seasons (spring, summer and winter) at the ARF. All fifteen rabbits were placed in cages to deter scavenging, but an additional rabbit was placed without a cage in Trial 1 to compare possible differences with unencumbered scavenger activity. Game cameras were placed in the study area to capture images of scavengers, document the process of scavenging, and identify which subject species were scavenged. Additional documentation of scavenging activity included daily photographs and notations of scavenging on the subjects, number of scavenger species and number of individual scavengers (when possible), and photographs of animal tracks on and around the subjects.

A total of four scavenger species were documented at the study areas, but their activities varied by season and by subject species. Raccoons were the most commonly observed scavenger, followed by birds (including robins, doves, and cardinals), opossum, and skunk. The birds fed upon the maggots, not subject tissues, while the other species did consume tissues. Raccoons are responsible for the majority of the scavenging. While the human subjects were scavenged in all three trials, the pigs and rabbits were only scavenged in the winter (Trial 3). Rabbit scavenging was limited to removal of fur from only two individuals in Trial 3 and there was no consumption, even though the raccoons could access the rabbits through the cages. All five human subjects were scavenged in Trial 3, but three of the humans were preferred by the raccoons who completed scavenging on these individuals prior to moving to the other two humans or to the pigs and rabbits. Only three of the five pigs were scavenged in Trial 3. The anatomical pattern of scavenging also varied between pigs and humans. Raccoon scavenging of humans typically began on the limbs and could include the head and thorax, while scavenging activity on pigs was limited to the head, neck, back, and abdomen. This reflects the anatomical differences between pigs and humans in terms of muscle (meat) distribution.

Seasonality is a key factor in scavenging for pigs and rabbits, but less so for humans. Although scavengers had access to the same species in the summer and fall, scavenging was most extensive in the winter. Allowed a choice, the raccoons preferred human remains and in some instances even showed preference for one cadaver over another. Thus, variation in scavenging intensity and pattern observed on the human subjects is not captured by the non-human study subjects.

This project was supported by the National Institute of Justice, Office of Investigative and Forensic Sciences, United States Department of Justice. The opinions, findings, and conclusions or recommendations expressed in this presentation are those of the researchers and do not necessarily reflect the views of the Department of Justice.

Forensic Anthropology, Scavenging, Taphonomy

A129 Analysis of Taphonomic Changes to Juvenile Pig Bone Exposed to a Marine Environment Using Non-Destructive Raman Spectroscopy

Jennifer L. McDowell, MSc, Sir John Walsh Research Centre, 71 Frederick Street, Dunedin 9016, NEW ZEALAND; Lynne S. Bell, PhD, Simon Fraser University, Dept of Criminology, 8888 University Drive, Burnaby, BC V5A 1S6, CANADA; and Keith C. Gordon, University of Otago, Dept of Chemistry, Union Place, Dunedin 9016, NEW ZEALAND*

After attending this presentation, attendees will understand how a shallow and inter-tidal marine environment affects juvenile bone preservation and will learn the benefits of using Fourier Transform (FT) -Raman spectroscopy to enhance bone analysis, without the need for time-consuming preparation or destruction of samples.

This presentation will impact the forensic science community by adding to the limited research currently available on time-dependent taphonomic changes to juvenile bone (pig) in a marine environment.

The ability to determine immersion time from bone condition is a critical forensic tool, but marine studies have lagged behind terrestrial ones and, in both cases, juvenile bones are far less studied than adult bones.

As forensic research seeks increasingly to exploit the information contained in bone, age-specific knowledge of taphonomic alteration in a marine environment is crucial. Alterations can occur as soon as the early postmortem period, so it is important to be able to distinguish and understand differential bone preservation. The objective of this study was to explore how the chemical composition of juvenile bone alters over time, using FT-Raman spectroscopy. Immersion time and level of submersion (full or partial) were the measured variables. Pig bone was used in this study as a proxy for human subadults, as both pig and juvenile human bone exhibit the presence of Haversian and plexiform bone. This is not a perfect model, but it is useful in examining the effect water has on bony substrate in lieu of the availability of human samples.

Piglet carcasses (*n*=40) were placed in the inter-tidal or sub-tidal zone, at the University of Otago Portobello Marine Laboratory located on Otago Harbour, Dunedin, New Zealand, for six months. This experiment was replicated to control for seasonality with pigs being placed at the start of the summer (January) and winter season (July) (total *n*=80). Every six weeks, five samples were collected from each zone; the tibia and femur were retrieved and air dried. To ensure consistent and comparable observations, the central bone shaft was chosen as the primary study area because the diaphyseal ends of many bones sustained significant damage. Each sample was scanned three times with an FT-Raman spectrometer, using 1,064nm excitation (1mm spot size, 250mW power). For analysis, particular attention was paid to the five main spectral peaks known to be associated with bone: PO_4^{3-} (960cm^{-1}); CO_3^{2-} (1,070cm^{-1}); CH_2 (1,450cm^{-1}); amide I (1,668cm^{-1}); and amide III (1,246-1,270cm^{-1}).

Using Principal Component Analysis (PCA) and linear discriminant analysis, from the spectral output, quantifiable differences were found between all variables, suggesting that there are both environment and time-specific changes occurring in the surface chemistry of the bone. Environment (inter-tidal and sub-tidal) could be separated with 88%-92% accuracy. In addition, separation by exposure time (6,12,18, and 24 weeks) was possible with 42%-70% accuracy when environment was known. PC loadings showed shifting and broadening of the PO_4^{3-} peak and an increase in CO_3^{2-} substitution into the hydroxyapatite, over time. An increase in CO_3^{2-} substitution creates disorder in the hydroxyapatite. Over time, the amide bands became less defined, indicating the breakdown of collagen. The change in the ratio of organic and mineral components was shown to be a key contributor for differentiating time. The presence of a carotenoid peak (1,525cm^{-1}) in inter-tidal, but not sub-tidal, samples appears to be a significant determinant in separating samples from the two environments and is indicative of algae growth. These results are a major step in better understanding how a marine environment affects juvenile bone and provides important information on the preservational trajectories of juvenile bone in a marine context.

Marine Decomposition, Juvenile Bone, Taphonomy

A130 The Skeletal Histo-Taphonomy of Deep Coastal Marine Submersion and Exposure

Lynne S. Bell, PhD, Simon Fraser University, Dept of Criminology, 8888 University Drive, Burnaby, BC V5A 1S6, CANADA; and Gail S. Anderson, PhD, Simon Fraser University, School of Criminology, 8888 University Drive, Burnaby, BC V5A 1S6, CANADA*

After attending this presentation, attendees will be aware of how pig carcasses, submersed in a cold marine water body, were affected at the microstructural level. Attendees will understand the experimental parameters and be able to recognize the specific "marine change" observed in bony microstructure.

This presentation will impact the forensic science community by explaining the effect of marine exposure to bone and illustrating how to identify associated taphonomic signatures that may be attributed as a result. This adds an important tier of new knowledge to a little-investigated area of forensic anthropology.

The microstructural preservation associated with marine exposure has been the subject of a small number of forensic studies. Work presented here represents the culmination of six deployments in a cold, deep coastal ocean body, the Salish Sea (in southwestern British Columbia and northwestern Washington), one of the world's busiest waterways. Pigs with weights between 16.3kg and 24.5kg, were freshly killed and placed in an experimental rig which deployed two pigs per deployment to the sea floor for an approximate period of six months. Lights and a High-Definition (HD) camera were turned on for a short period of time every 15 minutes per hour for the entire deployment period. Each deployment was at a different locale within the study area at differing times of the year.

Pigs proceeded to skeletonization in all cases, but this reduction did not proceed equally at each site in terms of time. Pigs were reduced within a period of days extending to months. Once recovered, pig bone was stored in seawater and transported within a 12-hour period to the laboratory where it was then washed with cold freshwater to flush out as much salt as possible, and allowed to air dry within the laboratory to stabilize. All pig bone recovered was jet black on recovery and within a 48-hour period would lose this coloration completely, becoming the white color considered normal for bone. The black color would partly be replaced by orange staining to the surface. During this time, bone was macroscopically screened using the ZEISS Stemi microscope. Bone that was untreated prior to freezing was also screened, and in no instance was there any evidence of biofilm. Washed mid-shaft femora and mid-shaft ribs, which had stabilized longer than four months, were prepared for light microscopy and three sequential transverse 80-micron sections were made for each bone using the Leica® microtome SP1600, mounted in **Digital Picture Exchange (**DPX) onto 35mm glass slides, and viewed on a ZEISS Axioscope.A1 using normal and circularly polarized light with a Light-Emitting Diode (LED) light source.

The results indicated that not all deployment environments rendered the marine tunneling observed in other studies; however, this tunneling was observed at different deployment sites and the tunneling dimensions were consistent with those observed by others as a characteristic constrained marine-change. Tunnels consistently had diameters of 5-7 microns and were peripheral to the outer cortex, were never seen on the medullary aspect, nor were they internal to the cortical osteonal systems. The observed orange staining was seen to minimally penetrate bone no deeper than 50-100 microns when present. Often this staining was associated with normal anatomical porosity and also with any postmortem tunneling present. No other microstructural change was observed in the pig bone and the bone had excellent internal preservation.

The results from this study indicate that the observed microstructural change is highly constrained in its morphology and the speed of this change occurred at some point during the six-month submersion period, most likely after soft tissue removal. Other studies have seen the penetrating depth of micro-tunneling extend more than 2mm into bone and dentine but, perhaps due to the short submersion period, such deep tunneling was never observed. Tunneling of other carbonaceous substrates has been speculated to be seasonally cyclical, with endoliths recolonizing as water conditions become favorable. Variation may also relate to rapid sedimentation where skeletal material becomes effectively covered, and this certainly happened with the experimental pigs; however, the change is not necessarily inevitable and further work is necessary to understand why this variation in tunnel depth exists with what is otherwise an important taphonomic indicator of marine submersion and exposure.

Marine, Bone, Taphonomy

A131 Taphonomy of the Perinate Skeleton: Redefining Structural Norms and Building Analytical Models

Christiane Baigent, MSc, Metropolitan State University Dept Sociology/Anthr, PO Box 173362, Campus Box 28, Denver, CO 80217-3362*

After attending this presentation, attendees will better understand the structural and analytical problems associated with preservation and the use of indices for scoring taphonomic change in the perinate skeleton.

This presentation will impact the forensic science community by presenting a modified, high-resolution method for documenting taphonomy in the perinate skeleton, as well as by introducing a novel method for standardizing criteria in the documentation and analysis of taphonomy.

The infant homicide rate in the United States has steadily increased over the past 45 years. The Center for Disease Control (CDC) reported 7.3 infant homicides per 100,000 in 2011 — a 75% increase since 1970.[1] The CDC further reports that the homicide risk is greater in the first year of life than in any other year of childhood before age 18.[1] Because they are easily concealed, difficult to recognize, easily relocated by scavengers, and may be further obscured by taphonomic processes within the post-deposition environment, the preservation of infant remains is often sited as the greatest investigative challenge. Analytical assumptions, such as the presumed "unachievable recovery" of perinate remains has hampered the development of analytical models, critical among which is the documentation of taphonomic change. This study seeks to introduce a modified, zone-based scoring system of indices to document taphonomic change in non-adult bone.

While the methodological frameworks utilized in bioarchaeology and forensic anthropology are often cyclically applicable, current models for analyzing and interpreting taphonomy in non-adult remains are insufficient for forensic investigation. This is largely due to methodological goals; while the bioarchaeologist strives to understand macroscopic socio-biological trends throughout blocks of deep chronological time, the forensic anthropologist is concerned with individualization in the present. Among the most pervading sentiments in the study of non-adults is that their skeletal remains suffer from poor, or a complete lack of, preservation; however, "preservation" is a loaded but often poorly defined term, the use of which may have very different implications in (bio) archaeological and modern context. The distinction between preservation (in the physical structural sense) and transport is critical to the forensic anthropologist who seeks to recover recently deposited remains. Therefore, it is not sufficient for the forensic anthropologist to rely upon simplistic models of preservation, nor should one passively fall back on assumptions associated with loss.

In an effort to quantify taphonomic change, Bello et al. propose the use of three indices to: (1) score the frequency of each bone in a sample (the Bone Representation Index); (2) express the quantity of skeletal material present (i.e., sum of anatomical number of bones) (the Anatomical Preservation Index); and, (3) evaluate the preservation of cortical surfaces as a ratio between sound cortical surfaces and damaged surfaces of each bone (the Qualitative Bone Index).[2,3] A method for increasing the resolution of these indices was developed in an effort to introduce precision and analytical homogeneity to the forensic analysis of the perinate skeleton. This study applied a modified, zone-based scoring system to a sample of 106 skeletons (represented by 371 long bones) from three geologically and temporally distinct archaeological sites within the United Kingdom. Zone scores were applied to two indices (termed the proportional anatomical preservation index and the proportional qualitative bone index). Further, following Waldron's proposal that specific operational definitions be applied to the diagnosis of disease in the skeleton to standardize criteria and facilitate valid comparisons between studies, a model termed "Qualitative Bone Filters" is proposed to serve a similar purpose in the application and documentation of categories of taphonomic change.[4]

The results indicate that "preservation" is highly dependant upon the index applied, and that resolution is effectively increased by the application of zone scores and qualitative filters. Additionally, a general pattern for the progression of taphonomic change commencing at the metaphyses was observed across all three sites. The consistent preservation of the epiphyseal interface was also observed and challenges assumptions surrounding "typical" patterns of degradation. These results indicate that the taphonomy of non-adult remains would be better understood if analytical methods are refined, standardized, and tailored to assess both intrinsic factors, such as the unique physiological and anatomical variables associated with distinct stages of development, and extrinsic factors, such as those inherent to the post-deposition environment.

Perinate, Taphonomy, Indices

A132 Using Satellite Telemetry to Study Vultures and Other Scavengers in Taphonomic Research

Lauren R. Pharr, PhD, 6634 Central Avenue Pike, Ste 102, Knoxville, TN 37912*

After attending this presentation, attendees will better understand the benefits and limitations of using satellite telemetry and Geographic Information Systems (GIS) in forensic contexts and taphonomic research. Satellite telemetry, or the remote Global Positioning System (GPS) satellite tracking of wildlife, provides location and altitude data on animal movements, such as vulture flight patterns.

This presentation will impact the forensic science community by providing new insight concerning: (1) whether or not vultures can be trained, then tracked as a way to locate human remains; and, (2) the methodological limitations of satellite telemetry when applied to studies involving terrestrial scavengers.

The circling vulture is a universal symbol of death, and these obligate scavengers use olfaction to search for fresh decay. In previous instances where individuals were reported missing, anecdotal accounts have suggested that investigators should search the area where circling vultures were seen; however, the circling vulture may be soaring within a wind vortex, or thermal, rather than about to scavenge a set of decaying remains.

To learn if vulture flight patterns can be used to identify vulture-scavenging locations, six vultures were trapped, GPS tagged, then released from the Texas State Forensic Anthropology Research Facility (FARF) in San Marcos, TX. The hourly locations of the vultures were monitored for six months and resulted in more than 15,000 GPS data points that included information on geographic location (distance), altitude, and flight speed. These variables were analyzed using GIS, allowing for the identification of scavenging behaviors in vultures.

Providing the ability to detect likely vulture scavenging locations from GPS tracking, satellite telemetry provides a wealth of information useful for advancing forensic taphonomy research. Nevertheless, limitations of satellite telemetry should be considered before a tracking study begins. These limitations include costs and logistical difficulties with trapping and tagging animals as seen in the examples below.

In 2014, a Medical Examiner (ME) consulted with this research regarding his plan to trap, train, and then release and track a GPS-equipped vulture to locate human decedents. Because vultures travel long distances, the idea of training a vulture to locate a human body in a fixed, small area is not realistic. For example, turkey vultures released from FARF traveled throughout Texas and into Oklahoma. Moreover, rather than a specific human or animal food source, vultures prefer to locate and scavenge fresh carrion by using their sense of smell. The benefits of the ME's proposal did not outweigh the costs in terms of time or finances.

Forensic anthropologists have suggested that the vulture tracking project be repeated using terrestrial scavengers such as coyotes. Based on experience, this could provide new insight concerning the distance a coyote could potentially travel with a bone from a forensic case; however, detecting the scavenging behavior of a coyote within the GPS data is a concern. For each vulture tracking location, GPS transmitters provided altitude and flight speed. Hourly changes in these two values allowed for the detection of possible scavenging locations; however, a coyote is always close to the ground, which makes it difficult to determine if a coyote is resting or scavenging. Therefore, the information that was most helpful in identifying the patterns in vulture behavior will be absent in terrestrial scavengers. Thus, satellite telemetry will not work as well for land scavengers because of the difficulty in identifying their scavenging behaviors.

Despite the limitations associated with GPS tracking research, with careful planning, a GPS study can provide new insight into scavenging behavior and substantially benefit the forensic community in solving cases for years to come.

This project was funded by the National Science Foundation (NSF), Louisiana State University (LSU) West-Russell Travel Grant, LSU West-Russell Materials Grant, and a Doctoral Dissertation Fellowship provided by the LSU Graduate School. The findings and opinions to be presented are those of the author and not necessarily those of either the NSF or LSU.

The use of migratory birds and other animals for research was conducted with federal, state, and university approval. All vultures were released unharmed and permits are available upon request.

GPS Tracking, Scavenger, Vulture

A133 Postmortem Intervals in Mice Submerged in Aqueous Environments at 20°C

Elizabeth N. Celata, MS, 42 Aldwick Rise, Fairport, NY 14450*

After attending this presentation, attendees will understand the variances in decomposition in aqueous environments such as marine and freshwater. The goal of this presentation is to encourage further academic study and experiments to study the decomposition rates in different water sources and soil samples globally.

This presentation will impact the forensic science community by reiterating and emphasizing the importance of continued research in aqueous environments due to continual changes in various water sources. The data obtained from this study demonstrates the differences in decomposition rate between the River Bourne and the English Channel within Bournemouth, United Kingdom; however, the need for an experiment which spans more than six weeks is noted to explore the possibility of variances increasing to the point of significance after a set point in time.

Aquatic environments offer a unique challenge in determining postmortem intervals. Water sources in the same region — even within a few miles of each other — can differ in salinity and overall mineral composition. Limiting confounding variables in a laboratory environment removes the variance in animal activity as well as temperature and light differences within the same environment due to depth. While aqueous submersion can impede decay in some aspects, submersion can also produce decomposition stages not seen in terrestrial burials. Submerged bodies have a greater likelihood of accelerated skin slippage with extended preservation of fatty tissues. Particular specimens were noted in this study to enter a gelatinous stage as a result of the varying speeds in internal and external decomposition.

To further understand the variances, 54 mice were submerged in marine water, freshwater, and a control environment at 20°C. The two water sources utilized for this study were from the surrounding area around Bournemouth, United Kingdom. The marine water was obtained near the Bournemouth Pier coastline on the English Channel while the freshwater was taken from the River Bourne, which runs into the channel. The 54 mice displayed sequential stages at differing rates over a six-week time period. Regression plots and comparative *T*-tests demonstrated that internal putrefaction rates, weight differences pre- and post-submersion, and abdominal circumference pre- and post-submersion of the aqueous environments differed significantly from the control group. The aqueous subjects did not vary significantly from each other quantitatively; however, the salinity of the marine samples resulted in differences visually which might not have occurred in a deeper container. The postmortem intervals were not consistent regardless of temperature or environment, though a clear variance was noted between the control and the submerged groups.

B1 Investigating the Use of MicroRNAs (miRNAs) for the Identification of Forensically Relevant Body Fluids

Kelsie R. Weir, BA, 9124 E Mill Creek Road, Troy, IL 62294; and Claire Glynn, PhD, Henry C. Lee College of Forensic Science, University of New Haven, West Haven, CT 06516*

After attending this presentation, attendees will gain insight into the field of miRNA analysis and its potential application to forensic science, in particular for body fluid identification. This presentation includes extensive research to identify the optimal method of miRNA extraction through to the validation of particular miRNAs previously suggested as markers for particular body fluids.

This presentation will impact the forensic science community by introducing the potential of this novel method for the confirmatory molecular identification of forensically relevant body fluids. This presentation will provide a valuable contribution to the growing field of miRNA analysis for body fluid identification.

MiRNAs are small, non-coding single-stranded RNA molecules, typically 19-25 nucleotides in length. Previously, they were assumed to have no function and were referred to as "junk DNA;" however, they are now known to play crucial roles in many biological processes and have been shown to be highly robust under chemical and physical conditions. Furthermore, through extensive research in the biomedical field, they have also been shown to have high tissue specificity, which infers great advantages to their role in the forensic science field.[1] Due to these qualities, it is proposed that miRNAs could be ideal for the identification of forensically relevant body fluids. The goal of this research was to investigate the ability to extract miRNAs from body fluids using multiple methods, and then to validate miRNAs previously identified to show specificity for particular body fluids using Relative Quantitative Polymerase Chain Reaction (RQ-PCR), which has been shown to be the gold standard for observation of miRNA expression.[2]

Following informed consent, five body fluids were collected from ten volunteers (n=50), including venous blood, menstrual blood, semen, saliva, and vaginal secretions. Each sample was extracted using three different methods including: mirVana™ miRNA isolation kit, miRNeasy® mini kit, and a modified mirVana™ method with Trizol. The manufacturer's instructions of each kit were followed throughout. The quality and quantity of extracted miRNA was determined using an Eon™ spectrophotometer which measures the full spectrum (220nm-750nm) for accurate measurement of concentrations (A260) and protein contamination (ratio A260/280). The concentration of each extracted sample was recorded in ng/µl and the quality assessed by analysis of the 260/280 ratio. RQ-PCR was performed using a 9700 Thermal Cycler and 7900HT Real Time PCR System, targeting six miRNAs of interest, namely miR-451, miR-412, miR-891a, miR-205, and miR-124a, with miR-16 used as the endogenous control. Data analysis was performed using Sequence Detection System (SDS) software and Mintab® 16.0.

The results of this study show that quantifiable miRNA was extracted from each sample; however, remarkable variation was observed in the yields obtained depending on the methods used for each body fluid. Overall, the results suggest the miRNeasy® mini kit provided consistently higher yields throughout all the body fluids, with the exception of saliva, where the modified mirVana™ method proved to be superior. Each miRNA of interest was detectable in the relevant body fluid with significant dysregulation observed across the body fluids for each miRNA.

This study has identified the optimal method for extraction of miRNAs from body fluids and further validates a selection of miRNAs previously suggested as potential biomarkers. This research highlights the overwhelming potential of miRNAs as novel molecular markers for the confirmatory identification of forensically relevant body fluids.

mircoRNA, Body Fluids, Identification

B2 The Effectiveness of Various Strategies to Improve DNA Analysis of Formaldehyde-Damaged Tissues From Embalmed Cadavers for Human Identification (HID) Purposes

Natalia Czado, MS, 43 Virginia Avenue, Woonsocket, RI 02895; Bobby L. LaRue, Jr., PhD, 3500 Camp Bowie Boulevard, Fort Worth, TX 76107; Amanda Wheeler, BS, 1105 Beasley Hills Lane, Houston, TX 77008; Rachel M. Houston, BS, 3505 Snidow Drive, Plano, TX 75025; Amy E. Sorensen, MSFS, 11 Webb Creek Place, The Woodlands, TX 77382; David A. Gangitano, PhD, Sam Houston State University, 13906 Paradise Valley Drive, Houston, TX 77069; and Sheree R. Hughes-Stamm, PhD, Sam Houston State University, Dept of Forensic Science, Huntsville, TX 77341*

After attending this presentation, attendees will better understand the effectiveness of various strategies to improve DNA typing from severely damaged and degraded Formalin-Fixed (FF) tissue samples for HID purposes.

This presentation will impact the forensic science community by suggesting that, rather than attempting to improve the quantity and quality of severely damaged and degraded DNA template (present in FF samples) prior to Short Tandem Repeat (STR) typing, a more productive approach for HID purposes may be to utilize Insertion/Deletion (INDEL) panels or Single Nucleotide Polymorphism (SNP) markers using Massively Parallel Sequencing (MPS) technologies.

FF tissues for genetic analysis may be obtained from autopsied or archived pathology samples, embalmed cadavers, or repatriated remains. STRs have been the gold standard markers for DNA HID for more than 15 years; however, after treatment with formalin fixatives, many samples are not successfully genotyped using STR analysis. Instead, other methods that pre-amplify the low amount of good quality DNA, repair the damaged DNA template, or use alternate genetic markers to amplify smaller target regions may generate more probative genetic information from these samples.

This study investigated the ability of three different Whole Genome Amplification (WGA) methods (GenomePlex® Complete WGA Kit; Illustra™ Ready-To-Go™ GenomiPhi™ V3 DNA Amplification Kit; and QIAGEN® REPLI-g FFPE Kit) plus one DNA repair treatment to improve downstream STR typing of FF tissues from embalmed cadavers.

In addition, the use of bi-allelic markers, such as INDELs and SNPs, were investigated. These markers, smaller than 200 base pairs (bp) in length, are less susceptible to degradation and therefore may also be more likely to amplify in highly damaged DNA, as in the case of FF tissues. The comparative Random Match Probabilities (RMP) of each sample using STRs, a battery of 39 INDEL markers, and a panel of 124 SNP markers using MPS for HID purposes (HID-Ion AmpliSeq™ Identity Panel) were examined.

This study presents the results of this work, in which none of the three WGA methods or the DNA repair treatment tested in this study consistently yielded more complete STR profiles than the untreated FF samples; however, when the RMPs of each sample obtained using the INDEL and SNP-based MPS panels were compared to those generated from the partial STR profiles obtained from non-treated FF samples, the INDEL and SNP markers generated notably lower RMPs, providing more robust DNA identifications.

Formalin-Fixed, INDELs, Massive Parallel Sequencing

B3 Tertiary Transfer of DNA by Examination Gloves Between Evidentiary Items at Crime Scenes

Marisa Teal Ketchum, BS, University of Indianapolis, 3767 S State Avenue, #210, Indianapolis, IN 46227; Erin L. Vollmer, BA*, University at Indianapolis, 4930 Rue Vallee, Apt 30, Indianapolis, IN 46227; Jenna Carnes, University of Indianapolis, 1400 E Hanna Avenue, Indianapolis, IN 46227; Krista E. Latham, PhD, University of Indianapolis, Biology Dept, 1400 E Hanna Avenue, Indianapolis, IN 46227; Cynthia Cale, BS, Strand Diagnostics, 5770 Decatur Boulevard, Ste A, Indianapolis, IN 46241; and Gay L. Bush, PhD, Strand Diagnostics, 5770 Decatur Boulevard, Ste A, Indianapolis, IN 46241*

After attending this presentation, attendees will better understand the potential for tertiary transfer of DNA among evidentiary items at a crime scene via examination gloves.

This presentation will impact the forensic science community by demonstrating potential routes for the cross-contamination of items collected during the course of processing a crime scene.

The increasingly high value placed upon DNA evidence has catalyzed the optimization of more sensitive equipment and chemistries utilized in the detection and analysis of DNA. While these advancements allow smaller quantities of DNA obtained from evidentiary items to be analyzed, they also increase the risk of detecting extraneous DNA that may not be associated with the criminal act. The process of collecting evidentiary items at the crime scene is one potential route of contamination. Protocols for evidence collection in the field, including how frequently gloves should be changed while processing a crime scene, vary among crime laboratories and personnel. The potential exists for the technician to transfer DNA among the items being collected at the crime scene via their examination gloves if not frequently changed.

The main learning objective of this pilot study is to investigate the possibility of transferring DNA among evidentiary items and to evaluate whether or not the amount of transferred DNA that is detected could complicate subsequent genetic analyses and interpretations. It is hypothesized that: (1) examination gloves can act as a vector for the transfer of DNA from one item to another; (2) the quantity of DNA transferred among items will decrease with each subsequent handling; and, (3) the quantity of DNA detected on each item will be at a level that is great enough to compromise the interpretation of DNA typing results.

A sterile plastic cup was handled by ungloved hands. A gloved laboratory technician handled this item (Tier 1) to swab for subsequent DNA analysis. The laboratory technician then handled a second sterile and untouched cup (Tier 2) without changing gloves, followed by a third cup (Tier 3). These items were also swabbed to detect any DNA that might have been transferred to the various cups during the handling process. This procedure was repeated a total of seven times with the laboratory technician changing gloves in between each trial. DNA extraction was conducted using the QIAGEN® QIAamp® DNA Mini Kit. The Quantifiler® Human DNA Quantification Kit in conjunction with an Applied Biosystems® 7500 Real-Time Polymerase Chain Reaction (PCR) instrument was used to estimate the quantity of human DNA present in each sample. Amplification was performed by PCR on an Applied Biosystems® 9700 thermal cycler. Amplified product was analyzed using capillary electrophoresis on an Applied Biosystems® 3130xl (16 capillary) instrument in conjunction with GeneMapper® ID (version 3.2.1).

Primary transfer DNA was detected on all Tier 1 cups, demonstrating the ease of transfer of DNA from an individual to an object. DNA was transferred to the technician's examination gloves and to the Tier 2 cups in 67% of the trials. A partial profile was obtained from one Tier 3 cup, which had the potential to interfere with interpretation. These results demonstrate the vulnerability of evidentiary items to cross-contaminate if examination gloves are not frequently changed at the crime scene. Therefore, the first hypothesis cannot be rejected. The second hypothesis cannot be rejected because the quantity of DNA detected on the items decreased as the laboratory technician handled the Tier 2 and Tier 3 items. Finally, the third hypothesis cannot be rejected since the alleles detected on the Tier 2 and Tier 3 items would interfere with the interpretation of the DNA profile results.

The results of this experiment demonstrate that although tertiary transfer did not occur in every trial, there is the potential for the cross-contamination of evidentiary items via examination gloves. The potential for tertiary transfer in the field should warrant caution during the handling of evidence due to the possibility of transferring an individual's DNA to an item not actually touched by that person. Crime laboratories and personnel should implement procedures to negate this possible route of contamination.

DNA, Tertiary Transfer, Examination Gloves

B4 Optimization and Validation of the ForensicGEM™ Rapid Extraction Method for High-Throughput Processing of Cotton Buccal Swabs

Kyleen Elizabeth Elwick, BS, 1079 Ridgecrest Drive, Goodlettsville, TN 37072; Sheree R. Hughes-Stamm, PhD, Sam Houston State University, Dept of Forensic Science, Huntsville, TX 77341; Kimberly S. Andreaggi, MFS, ARP/AFDIL, 115 Purple Heart Drive, Dover AFB, DE 19902; and Michelle A. Peck, MFS, Armed Forces DNA Identification Laboratory, 115 Purple Heart Drive, Dover AFB, DE 19902*

After attending this presentation, attendees will understand the benefits of using forensicGEM™ as an optimal extraction method for the High-Throughput (HTP) processing of reference samples.

This presentation will impact the forensic science community by demonstrating an HTP, rapid extraction method that decreases the time and cost of extraction. By removing the need for lengthy extraction protocols, this method will assist in the elimination of reference backlogs in forensic laboratories.

Most extraction methods are time consuming and have a high risk for contamination due to numerous steps involved in the purification of the DNA. The Armed Forces DNA Identification Laboratory (AFDIL) currently uses DNA IQ™ for HTP processing of cotton buccal swabs, which is expensive and time consuming. The forensicGEM™ method uses a proteinase from the thermophilic *Bacillus* sp. EA1 and robust buffers to perform a single-step extraction in approximately ten minutes without the need for purification. ForensicGEM™ chemistry is rapid, compatible with downstream processing methods, adaptable to tubes or plates, amenable to automation, and inexpensive. The ability to do a single-step extraction without purification will facilitate the rapid low-cost HTP processing of cotton buccal swabs.

For use at the AFDIL, the forensicGEM™ Storage Card (Saliva) kit was optimized and validated for HTP processing of cotton buccal swabs. The optimization experiments examined three steps in the procedure: (1) cell elution; (2) eluate input volume; and, (3) extraction buffer volume. First, the five-minute elution step, which is performed in a ThermoMixer® C to dislodge the buccal cells from the swabs, was evaluated at two different speeds: 900rpm and 2,000rpm. These two conditions were each tested on 90 buccal samples to assess DNA yield and the impact of the swab position on the 96-well plate. Agitating samples at 2,000rpm corresponded to a 79% success rate (full profiles) when typed with AmpFℓSTR Yfiler®, whereas agitating swabs at 900rpm demonstrated only a 46% success rate. Plate location of the buccal swab appeared to make no difference in the success of profiles. Based on these results, 2,000rpm was determined to be the optimal elution condition.

Next, the volumes of the eluate input and extraction buffer were also investigated to further improve DNA yield. Cotton buccal swabs were collected from a total of 15 sources (in duplicate) and were extracted using five extraction conditions, testing a range of 40µL-100µL of eluate with a range of 10µL-25µL of buffer. The extracts were evaluated with several commercially available Short Tandem Repeat (STR) kits as well as the Control Region (CR) of the mitochondrial DNA (mtDNA) genome. The extraction condition that used 70µL of eluate input with 10µL of forensicGEM™ buffer outperformed the other conditions, generating at least a 90% first pass success rate with CR amplification and all STR kits. The STR profiles were of high quality (e.g., optimal peak heights, low intracolor imbalance) and required minimal reprocessing. This performance mimicked current processing methods and was therefore selected as the optimized protocol. Further testing is currently being performed to validate the optimized forensicGEM™ method for sensitivity, repeatability, and reproducibility according to the Scientific Working Group on DNA Analysis Methods (SWGDAM) guidelines using quantitative Polymerase Chain Reaction (PCR), STR typing, and mtDNA analysis. Implementation of this optimized HTP extraction will allow for increased throughput capabilities by reducing both costs and processing time by approximately 65%.

Rapid Extraction, DNA Databasing, ForensicGEM™

B5 Investigating Simultaneous Extraction of RNA and DNA From Forensically Relevant Body Fluids

Sarah L. Markland, 300 Boston Post Road, West Haven, CT 06516; Kelsie R. Weir, BA, 9124 E Mill Creek Road, Troy, IL 62294; and Claire Glynn, PhD, Henry C. Lee College of Forensic Science, University of New Haven, West Haven, CT 06516*

After attending this presentation, attendees will be aware of the potential of the simultaneous extraction of microRNA (miRNA) and DNA from within a single sample for forensically relevant body fluids. This includes the investigation and comparison of two commercially available co-extraction kits for the yields obtained from each kit, the sensitivity of each kit, and the ability to obtain both miRNA and DNA profiles.

This presentation will impact the forensic science community by highlighting the usefulness of co-extracting RNA and DNA from a single sample. This method could lead to both confirmatory body fluid identification and human DNA profiling.

MiRNAs are a class of short non-coding RNA molecules which are approximately 22 nucleotides in length and regulate the post-transcriptional gene expression in many eukaryotes. It has recently been suggested that miRNAs could serve as potential biomarkers for body fluid identification in forensic investigations. Previously, messengerRNA (mRNA) was proposed as a useful tool for body fluid identification; however, due to their instability and susceptibility to degradation, they have not shown great promise in the forensic field. In contrast, miRNAs are remarkably robust and infer great stability due to their small size; however, depending on the volume of sample available, the miRNA analysis could consume the sample and potentially eliminate the ability to obtain a DNA profile. Therefore, there is a great need for a method which performs both RNA and DNA extraction simultaneously from one sample. There have been limited advancements in this area with only a few commercial methods currently offered for this purpose. Little research has been performed on this topic in the forensic setting. The goal of this study was to investigate two commercially available co-extraction RNA/DNA kits by examining the quality and quantity of RNA/DNA extracted, followed by a series of dilutions to test sensitivity, and finally by the ability to obtain a miRNA signal and DNA profile from a range of forensically relevant body fluids.

Following ethical approval from the Institutional Review Board and informed volunteer consent, venous blood, semen, saliva, and urine were collected from five volunteers (n=20). The two commercially available kits that were investigated were the Zymo Research ZR-Duet™ DNA/RNA MiniPrep kit and the QIAGEN® AllPrep™ DNA/RNA Mini Kit. The manufacturer guidelines were followed for each kit. First, neat samples were extracted from 200µl of each body fluid using each kit. Following this, a series of dilutions of each body fluid were created in 1:2, 1:10, 1:25, and 1:50 ratios and then the co-extraction of miRNA and DNA were performed using the same kits. Following RNA/DNA extraction, all eluates were analyzed to determine the RNA/DNA concentration in each sample. This was achieved using Biotek Eon™ spectrophotometer which measures the full spectrum (220nm-750nm) for accurate measurement of concentrations (A260), protein contamination (ratio A260/280), and contamination with buffer components or organic compounds (ratio A260/A230). The concentration of each extracted sample was recorded in ng/µl and quality assessed by analysis of the 260/280 ratio. In the final step, Relative Quantitative Polymerase Chain Reaction (RQ-PCR) was performed on a selection of the RNA samples targeting miR-16 to determine if a miRNA signal was present within the extract. In parallel, STR analysis was performed on a selection of the DNA samples to obtain full human DNA profiles.

The results showed that quantifiable amounts of both DNA and RNA were obtained in the neat samples of all the body fluids using both kits; however, the concentrations obtained were highly variable depending on the particular body fluid and the particular kit used. The results obtained from the diluted samples produced varying concentrations at much lower levels, as expected. Overall, the Zymo Research kit proved to obtain higher concentrations of both DNA and RNA when compared to the QIAGEN® kit. Finally, miRNA signals and full DNA profiles were obtained from all samples selected for miRNA/DNA profiling.

In conclusion, this study reveals the ability to successfully co-extract both RNA and DNA from forensically relevant body fluids, suggesting the Zymo Research kit as a superior method for this purpose. This research highlights the potential of miRNAs for the identification of forensically relevant body fluids as it has shown to be possible the ability to extract both miRNA profiles and DNA profiles from a single sample, which could prove crucial to a forensic investigation.

MicroRNA, DNA, Co-Extraction

B6 Investigating the Use of Raman Spectroscopy for the Differentiation of Mixed Body Fluid Samples

Tyler J. Schlagetter, 441 Lunar Street, Sidney, OH 45365; Brooke W. Kammrath, PhD, University of New Haven, Forensic Science Dept, 300 Boston Post Road, West Haven, CT 06516; and Claire Glynn, PhD, Henry C. Lee College of Forensic Science, University of New Haven, West Haven, CT 06516*

After attending this presentation, attendees will be aware of the potential of Raman spectroscopy to be integrated into forensic body fluid analysis. This includes its use in both identifying individual fluids, differentiating between fluids in mixed samples, and analyzing samples found on different substrates.

This presentation will impact the forensic science community by discussing the advantages and limitations of Raman spectroscopy with regard to its use in the identification and analysis of body fluids and their mixtures.

In forensic investigations, stains recovered from crime scenes can often be a combination of different body fluids (e.g., semen and saliva, or blood and saliva). With the success of forensic DNA typing over the past three decades, there are several strategies for the successful resolution of DNA mixtures; however, there has been little research into effective analytical methods for the resolution of mixtures of body fluids. While there are certain methods currently employed for the confirmatory identification of body fluids, many of these are destructive (in terms of consuming the sample), some have variable results and are labor intensive, while none have the capability of separating two body fluids in one sample. The non-destructive capabilities of Raman spectroscopy have allowed it to become a growing source of interest in the forensic science profession. Research has shown that Raman spectroscopy produces spectra which can be used to identify blood, semen, saliva, vaginal secretions, and sweat without consuming the sample.[1] The goal of this study was to investigate the use of Raman spectroscopy to identify the individual body fluids comprising a mixed body fluid sample.

Following informed consent, venous blood, semen, saliva, and urine were collected from five volunteers (n=20). Raman spectroscopy with a 785nm excitation wavelength under controlled laboratory conditions was performed on the individual body fluids, followed by body fluid mixtures of varying ratios. The body fluids were also tested on a variety of substrates (aluminum slide, black cotton, and white cotton). Last, DNA profiling was performed on a selection of the scanned samples to investigate the ability to obtain a DNA profile post-Raman analysis.

The results showed that each of the body fluids produced their own individual spectra. Mixture testing revealed that detection of both body fluids was possible with blood and semen, saliva and semen, saliva and urine, and semen and urine mixtures; however, the results indicated that the blood gave too strong a Raman signal to allow for saliva or urine to be fully detected. The substrate analysis revealed that blood was the only body fluid partially detected and was only detected on the white cotton. All mixtures tested on the substrates gave indefinite results due to interference from the substrates. Full DNA profiles were obtained from all samples tested.

This study reveals the successful use of Raman spectroscopy for the resolution of a number of mixed body fluid samples and highlights the potential of the technique to be introduced as a novel, non-destructive method for the identification of forensically relevant body fluids.

Raman, Mixtures, Body Fluids

B7 The Identification of Biological Fluids Based on DNA Methylation Differences Using High Resolution Melt Curve Analysis

Susan Cheng, BS, 100 College Drive, Allentown, PA 18104; and K. Joy Karnas, PhD, Cedar Crest College, 100 College Drive, Allentown, PA 18104*

After attending this presentation, attendees will understand how high resolution melt curve analysis may be used to distinguish between biological fluids using DNA methylation patterns that differ between cell types.

This presentation will impact the forensic science community by providing a novel method of potentially distinguishing menstrual blood and peripheral blood, as well as differentiating deposited vaginal fluid, saliva, and semen stains. In addition, methylation analysis uses the same DNA extraction protocol as Short Tandem Repeat (STR) typing, making these two methods compatible for side-by-side analysis.

Identifying the origin of the biological fluid is important in crime scene reconstruction and provides information to link evidence to the crime. Traditional methods of identifying body fluids rely on proteins for identification and are initially presumptive in nature. Presumptive tests may not be reliable due in part to cross reactivity with other biological fluids, resulting in false positives. In addition, false negatives may result due to degradation of protein antigens by heat and humidity. Once a stain presumptively tests positive for a biological fluid, an additional confirmatory test is necessary in order for the evidence to have legal and scientific standing in a court of law. Due to time and budgetary constraints as well as insufficient amounts of sample, confirmatory assays are not always able to be performed by forensic laboratories.[1] DNA methylation markers and pyrosequencing have recently been evaluated as an alternate method for body fluid identification. While these studies were able to discriminate the specific body fluid, pyrosequencing is expensive and uses equipment that is not available in most forensic laboratories.[2]

This study is a continuation of previous research that differentiated semen from other body fluids using DACT1 primers.[3] In this study, menstrual blood, blood, vaginal fluid, saliva, urine, sweat, and semen samples were obtained from volunteers by self-collection. An organic extraction was used to isolate DNA from each swab prior to subjecting the DNA to bisulfite conversion, which converts unmethylated cytosines to uracil, using a Zymo Research EZ DNA-Methylation-Lightning™ kit. High resolution melt curve analysis was carried out to analyze the melting temperature of the amplicons containing known sites of differential DNA methylation patterns using the QIAGEN® EpiTect™ High Resolution Melt Polymerase Chain Reaction (PCR) Kit. Primers used in this study are either proprietary or previously published.

Results from this study indicate that the HOX-B6 primer distinguished four out of ten menstrual blood samples from circulating blood samples. The primer also distinguished five out of ten vaginal fluid samples from other biological fluids (including blood, saliva, urine, and sweat). Using the SOX2OT primer, seven out of ten saliva samples were differentiated from other biological fluids (including menstrual blood, blood, vaginal fluid, urine, and sweat). This indicates that when samples are analyzed in tandem using the HOX-B6, SOX2OT, and DACT1 primers, menstrual blood, vaginal fluid, saliva, and semen may be differentiated from other body fluids.

Forensic Science, DNA Methylation, Biological Fluids

B8 Analysis of Attenuated Total Reflectance/Fourier Transform Infrared (ATR/FTIR) Spectra to Differentiate Menstrual and Venous Blood on Various Substrates

Alicia Quinn, BS, 120 Stoney Meadow Lane, Madison Township, PA 18444; and Kelly M. Elkins, PhD*, Towson University, Chem Dept & Forensic Science Program, 8000 York Road, Towson, MD 21252*

After attending this presentation, attendees will better understand ATR/FTIR spectroscopy and how this method can be used to analyze spectra for body fluid samples on various substrates and differentiate venous and menstrual blood following statistical analysis.

This presentation will impact the forensic science community by suggesting a rapid, non-destructive method for differentiating body fluid samples, including venous and menstrual blood, on various substrates that can provide significant discriminatory information for forensic comparisons.

Body fluids are often encountered at crime scenes, especially those in which sexual and violent crimes have been committed. An alternate light source is often used to locate the presence of body fluids but is not used to identify them. Chemical methods are typically employed to tentatively identify the presence of body fluids including blood, semen, saliva, urine, and fecal matter. A drawback of using chemical methods is that they may dilute the sample, cause degradation, or interfere with DNA typing. ATR/FTIR spectroscopy has been suggested as a method that can be used to identify and differentiate body fluids in simulated forensic samples; however, only neat samples and samples on white paper and white cotton substrates were tested.

This study evaluated the entire ATR/FTIR spectrum (including the amide banding and fingerprint regions) for the body fluid samples on several substrates including colored cotton, polyester, nylon, wood, and glass. Blood, semen, and breast milk standard samples were purchased from Lee™ Biosolutions. Saliva and menstrual blood samples were obtained from healthy donors in accordance with Towson University Institutional Review Board (TU IRB) approval. A Thermo Fisher Scientific Nicolet™ iS™10 spectrometer with a Smart iTR™ ATR attachment and equipped with the Omnic™ software version 32 was used to collect all spectra. ATR/FTIR absorbance spectra (128 scans, 4,000 to 400cm-1 spectral range, 1.929cm-1 spectral resolution) were recorded using the ATR diamond crystal in ambient temperature with air as a background. A standardized volume of 20µL of each type of body fluid was deposited onto parafilm and dried at room temperature. The residue layer was applied directly to the cleaned diamond crystal surface. Separately, the neat body fluid samples were pipetted (20µL each) onto five different substrates. Reference spectra were recorded of each substrate and subtracted to identify contribution from the body fluid. Three replicates of each fluid were performed. The average signal was averaged over all scans and the data was saved as a .csv text file for import into Microsoft® Excel® for spectral analysis. Statistics were used in order to differentiate the body fluids from one another by looking at the presence or absence of a particular wavenumber (cm-1) as neat samples and on the surfaces. The statistical technique emphasizes the variations and draws out strong patterns in the dataset. Variations of the body fluid spectra provide significant discriminatory power and provide support for ATR/FTIR to be investigated further as a method that could be employed at the crime scene.

ATR/FTIR, Venous Blood, Menstrual Blood

B9 Touch DNA Recovered From Fired and Unfired Shotgun Shells

Anthony J. Saitta, 57 Guernsey Lane, New Milford, CT 06776; and Peter R. Valentin, MSFS, University of New Haven, Forensic Science Dept, 300 Boston Post Road, West Haven, CT 06516*

After attending this presentation, attendees will better understand the potential implications of touch DNA as it relates to cartridge casings and the impact of the firing process on the ability to recover DNA.

This presentation will impact the forensic science community by providing statistical data from a well-controlled experiment, thus increasing the information gathered on the applications of touch DNA. With more sensitive DNA testing, this information will help redefine the areas and objects that can be tested for DNA.

Over the last decade, major advancements have been made in the field of touch DNA recovery; however, some challenges still exist. In particular, the recovery of touch DNA from firearm cartridge casings has long been regarded as a difficult task with minimal yields expected. This project was designed and conducted to generate valid statistical data on the recovery of touch DNA from both fired and unfired shotgun shells. Modeled after similar experiments, the goal of this study was to expand the data gathered on touch DNA and its applications. This study hypothesized that there would be a higher yield of DNA recovery from plastic shotgun shells than from metallic pistol or rifle cartridge casings. Based on the principles of organic compound interactions, fingerprint oil is expected to adhere better to the low-density polyethylene of the shotgun shell compared to metals such as brass or copper, thus leaving behind more skin cells to be collected and DNA to be extracted. Additionally, it was hypothesized that the unfired shells would yield a higher recovery of DNA, as they were not exposed to the extreme heat generated during the firing process.

In this experiment, 90 12-gauge shotgun shells were collected and examined for the presence of touch DNA. Three participants each loaded and fired 15 rounds, then loaded and ejected 15 rounds without firing. The shells were loaded each time in groups of five, carefully ejected directly into pre-labeled evidence bags, and immediately sealed. Under sterile laboratory conditions, all samples were swabbed using the double-swabbing method: one sterile cotton swab wet with sterile water, followed by one dry sterile cotton swab. These swabs were then extracted using a QIAGEN® Investigator® extraction kit, followed by 40 cycles of Polymerase Chain Reaction (PCR) amplification. After quantification, approximately 17.78% of the unfired samples and 18.60% of the fired samples extracted and quantified yielded sufficient DNA for a partial or full profile. Results of a previous project stated the recovery rate of DNA from brass casings, both fired and unfired, was approximately 36%, while nickel-plated pistol cases only yielded 12%, fired and unfired. Therefore, the results from this study, revealing approximately 18.2% recovery from plastic shotgun cartridges, provides a valuable contribution to the investigation of touch DNA recovery from firearm cartridge casings.

This study gathered controlled statistical data on the recovery rate of touch DNA from fired and unfired shotgun shells, increasing the knowledge of touch DNA and its new potential areas for testing.

Touch DNA, Shotgun, DNA

B10 Use of Massively Parallel Sequencing to Assist With Deconvolution of Short Tandem Repeat (STR) Mixture Profiles

Kelly Grisedale, PhD, Western Carolina University, 111 Memorial Drive, NSB 231, Cullowhee, NC 28723; Jessica Bradley, BS, Western Carolina University, 111 Memorial Drive, NSB 231, Cullowhee, NC 28723; Brittania J. Bintz, MSc, 111 Memorial Drive, NSB 231, Cullowhee, NC 28723; and Mark R. Wilson, PhD, Western Carolina University, Dept of Chemistry/Physics, Forensic Science, Cullowhee, NC 28723*

After attending this presentation, attendees will better understand how DNA samples amplified with traditional fluorescence-based STR kits can be further interrogated using Massively Parallel Sequencing (MPS) to assist with interpretation of low template or mixed DNA profiles.

This presentation will impact the forensic science community by providing an avenue to gain maximum information from mixture samples that are traditionally difficult to interpret with standard DNA profiling techniques.

Forensic DNA profiling by Polymerase Chain Reaction (PCR) of STR is considered a robust and reliable method of human identification. STRs are highly discriminating, and the exponential amplification of the PCR allows for complete profiles to be obtained from as little as 200pg of DNA; however, difficulties can arise in profile interpretation when the starting DNA template is extremely low or if the profile contains DNA from more than one contributor.

Mixture DNA profiles can be especially difficult to interpret when the contributors share alleles. In cases where one individual in the mixture contributes considerably more genetic material than the other individual, the major contributor can mask the profile from the minor contributor, making it nearly impossible to deconvolute shared alleles.

Current methods of STR analysis only provide information regarding the STR fragment length; however, sequencing of STRs could provide further information to assist with deconvolution of mixture profiles. Initially, reads attributed to each STR locus are sorted based on flanking sequences adjacent to the targeted repeat. Repeats contained within each read are counted by the software, and resulting counts are used to calculate an approximate mixture ratio, enabling parsing of alleles to each contributor. Shared alleles can also be deconvoluted. STR fragments may contain Single Nucleotide Polymorphisms (SNPs) that would not be detected with traditional Capillary Electrophoresis (CE) genotyping analysis. Furthermore, many STRs have been shown to have different configurations of repeated units for the same allele.

This presentation proposes a method to use MPS methods to sequence PCR product generated using a commercial STR kit designed for traditional CE analysis. While STR kits designed specifically for MPS are in development, the ability to sequence previously amplified samples could provide further insight into profiles that were difficult to interpret with STR length information alone.

Single-source and two-person mixture samples of various mixture ratios were amplified with the GlobalFiler™ PCR amplification kit. All samples were run on the 3500xL Genetic Analyzer to obtain reference electropherograms. The same PCR product was then prepared for MPS using enzymatic library preparation via tagmentation by Nextera® XT followed by deep sequencing on the Illumina® MiSeq®. Data were then analyzed using STRait Razor software.

Preliminary results indicate that the Nextera® tagmentation step successfully removes the fluorescent tags incorporated into the PCR products during amplification with the GlobalFiler™ kit. This is essential for successful sequencing on the MiSeq®, since this sequencing-by-synthesis method involves fluorescence detection. Furthermore, analysis of the STR sequences in mixed DNA profiles has revealed some different STR sequence motifs for shared alleles that are kept in relatively similar proportions as would be expected from the ratio of input DNA from the two contributors. This has allowed some shared alleles that were initially masked in the reference electropherogram to be assigned to the major or minor contributor.

Massively Parallel Sequencing, Short Tandem Repeats, Mixtures

B11 Absolute Quantitation of Semen-Specific Biomarkers From Post-Coital Samples

Catherine O. Brown, BA, Arcadia University, 450 S Easton Road, Glenside, PA 19038; Masha Signaevsky, BS, Arcadia University, 423 Roslyn Avenue, 2nd Fl, Glenside, PA 19038; Heather E. McKiernan, MSFS, Center for Forensic Science Research & Education, 2300 Stratford Avenue, Willow Grove, PA 19090; Kevin M. Legg, 2300 Stratford Avenue, Willow Grove, PA 19090; and Phillip Danielson, PhD, Department of Biology, 2101 E Wesley Avenue, Lab 223, Denver, CO 80210*

After attending this presentation, attendees will better understand the use of a multiplex tandem mass spectrometry assay for the detection of seminal fluid protein biomarkers that will be of benefit in the determination of the post-coital interval for semen detection.

This presentation will impact the forensic science community by providing results from a quantitative study in an area of forensic science that is under-researched. The results of this study have the potential to aid in determining the post-coital interval, which can further assist sexual assault forensic examiners in the timely collection and processing of sexual assault evidence.

Sexual assault is a prevalent crime in today's society; however, the forensic testing utilized for sexual assault evidence is costly and time consuming, resulting in a backlog of untested evidence. The current enzyme-activated and antibody immunochromatographic tests used by forensic examiners for the identification of seminal fluid only provide presumptive results. This is due to false positives with non-biological material, cross-reactivity, and positive results with non-target fluids. Immunochromatographic tests rely on the tertiary structure of proteins in order to produce positive results; however, proteins may be subjected to undesirable conditions resulting in the unfolding of the tertiary structure, preventing enzyme or antibody interaction. A negative serological test may prevent the sample from receiving additional DNA testing, regardless of whether the protein was present in a degraded form. The presumptive nature of these tests has deterred scientists from reliably determining a post-coital interval. The development of a confirmatory technique for the identification of seminal fluid would allow for the post-coital detection of semen to be determined and would assist in the analysis of sexual assault evidence.

Prior experiments have identified, developed, and validated a qualitative, mass spectrometry-based assay for the confirmatory identification for human seminal fluid. A previously performed sensitivity study has shown that seminal fluid biomarkers (prostatic acid phosphatase, prostate specific antigen, and semenogelin) are readily detectable by mass spectrometry from a little as 1nL of semen, levels at which the currently employed presumptive tests begin to fail.

The goal of the current research was to validate a quantitative variation of the previously developed method in order to quantitate these semen-specific proteins in post-coital samples. The current method employs scheduled multiple reaction monitoring on an Agilent® 6430 triple quadrupole mass spectrometer coupled with a nanoflow chip cube High-Performance Liquid Chromatography (HPLC). Using synthetic peptide standards, a linear calibration model was developed and mock casework samples were used to analyze the multiplex assay's sensitivity and limits of detection in addition to a comparison of the specificity and selectivity of this approach to immunochromatographic assays.

In conclusion, this study provides evidence that mass spectrometry produces more sensitive results for the detection of seminal fluid, providing a more reliable method for the detection of semen in sexual assault samples. Furthermore, the use of mass spectrometry has the potential to enhance the serological screening process and aid in the determination of the post-coital interval.

Forensic Science, Proteomics, Seminal Fluid

B12 Rapid Direct Polymerase Chain Reaction (PCR) of a Y-Chromosomal Short Tandem Repeat (Y-STR) Multiplex as a Screening Tool for the Presence of Male DNA

Bruce R. McCord, PhD, Florida International University, Dept of Chemistry, University Park, Miami, FL 33199; and Georgiana C. Gibson-Daw, MS, 8920 NW 8th Street, Apt 518, Miami, FL 33172*

After attending this presentation, attendees will better understand how the use of rapid direct PCR along with microfluidic separation and specially designed Y-STR multiplexes can screen crime scene samples for the presence of male DNA and thus aid in the analysis of time-sensitive cases.

This presentation will impact the forensic science community by providing results that show how the amount of time and reagents used can be vastly decreased with a combined rapid and direct PCR screening method on which little research has been performed. This presentation will add to the body of research being carried out in forensic DNA analysis that focuses on reducing the amount of time and steps involved in sample analysis. This would enable more samples to be run in a determined amount of time, thus increasing throughput. In addition, the removal of the extraction step would decrease the potential for sample loss and in-laboratory contamination, both of which are important problems when dealing with samples from a crime scene.

It is often extremely important to rapidly screen crime scene samples and unknown individuals who may have been involved in a crime, namely in situations where many samples may need to be run for sorting through excessive amounts of evidence or before detention of a suspect is possible. Examples include seized evidence potentially linked to a suspect or the determination of which blood stains present at a crime scene may be probative.

Mass disasters in particular create a need for rapid, inexpensive screening of DNA samples with a minimum of sample pretreatment. Recently developed DNA typing methods provide the best biometric information for identity, kinship, and geographical origin, but they are not sufficiently fast to permit the detection of a suspect's DNA in real time. Rapid direct PCR procedures can greatly accelerate the processing time because no extraction is necessary.[1-6] This decrease in processing time and reagent volumes leads to a quick turnaround and inexpensive processing of larger numbers of samples. Such procedures have previously been designed for STRs.[7, 2-3] The goal of this project is to develop a rapid and direct method for profiling Y-STRs as a fast and effective screening tool to determine the presence of male DNA in collected samples.

To do this, specially engineered enzymes, high speed thermal cyclers (capable of running 28 cycles in less than 14 minutes), and microfluidic chip-based electrophoresis will be implemented to process a specifically designed Y-STR multiplex.[1, 8-14] The goal is to reduce the analysis time to less than 25 minutes.[7] The designed multiplex includes four Rapidly Mutating (RM) Y-STRs (DYS526a/b, DYS576, DYS626, and DYS570) between 137bp and 402bp in size, with mutation rates of 10^{-2} per meiosis or greater. By using off-the-shelf instruments and commercially available enzymes, it is possible to create a procedure that acts as a quick, highly informative sample-screening process that also retains sufficient DNA for later manual processing using standard STR or Y-STR kits.

In the first phase of this study, a 4-locus Y-STR multiplex was designed and utilized on a conventional 310 Capillary Electrophoresis (CE) and a beta version of a denaturing Microfluidic Electrophoresis (ME) system. This was tested on control DNA standards 2800M Control DNA and HY DNA as well as with donated saliva samples from five adult males. The multiplex was then analyzed using a rapid PCR protocol, using a variety of rapid polymerases in an effort to optimize the speed and balance of the amplification. This procedure was further optimized with the use of Z-Taq and a direct PCR buffer (Any Direct F buffer) to obtain a rapid direct PCR method, which when coupled with microfluidic separation cuts down sample analysis time to less than 40 minutes, with the possibility of decreasing this further.

The results of this study demonstrate the application of rapid direct PCR for the analysis of Y-STRs for evidence screening. Because the process utilizes a small set of rapidly mutating Y-STR loci, it can also provide useful preliminary data on the presence of male DNA for use in suspect identification.

Rapid PCR, Direct PCR, Microfluidic Y-STR Analysis

B13 Determining the Most Efficient Location for Collecting DNA Samples From Hand Guns

Kaitlyn M. Redman, BS, 190 Robin Ridge Road, Feeding Hills, MA 01030; Kathryn E. Hoodenpyle, MS, 425 E Phelps Street, Springfield, MO 65806; Jill Therriault, BS, Connecticut Department of Emergency Services, Division of Scientific Services, 278 Colony Street, Meriden, CT 06451; Arielle Van Deusen, BS, CT Department of Emergency Services, Division of Scientific Services, 278 Colony Street, Meriden, CT 06451; Jessica Best, MSFS, Connecticut Forensic Lab, 278 Colony Street, Meriden, CT 06451; and Michael S. Adamowicz, PhD, University of New Haven, Dept of Forensic Science, 300 Boston Post Road, West Haven, CT 06516*

After attending this presentation, attendees will better understand the most effective locations to collect samples from hand guns for forensic DNA testing. This study presents data regarding the quantity and quality of DNA recovered from discrete locations on semi-automatic and revolver-style hand guns. It also presents data contrasting the collection of DNA from "overall" swabbing of a firearm versus targeted area collections.

This presentation will impact the forensic science community by providing further experimental data regarding the optimal strategy to use when collecting samples from hand guns for DNA analysis. This data will assist analysts with targeting the areas on hand guns that are most likely to yield the highest quantities of DNA for Short Tandem Repeat (STR) analysis while avoiding collecting wasteful extra samples that show poor results.

DNA recovery from firearms was evaluated in order to determine the most efficient location(s) for the collection of DNA evidence. Previously cleaned firearms (Glock® 19, Beretta® 92, Smith & Wesson® 10-5, and Taurus® Ultra-Lite) were handled for approximately one hour, including having the actions repeatedly worked and then discharged prior to sample collection using a double-swab method (moistened and dry). Results from the individual area swabs of two revolvers and two semi-automatic pistols were compared to an overall swabbing strategy. The areas of focus for both types of hand guns were the backstrap, grip, trigger, and front sight blade. Samples were also collected from the revolvers' cylinder and hammer and the semi-automatic pistols' slide and magazine.

Standard methods of DNA analysis utilized in forensic laboratories were used, including quantification and amplification. All cleaned firearms were checked for background DNA using control swabbings prior to each handling cycle. Each collection area was first assessed by the average recovered yield of DNA. DNA profiles were then generated and analyzed by comparing the sample profiles to known profiles obtained from the firearms' handlers. Profiles were assessed by examining the total number of alleles out of the possible 30 and total number of complete loci out of 15. Profiles with less than ten loci present were processed with the MinElute® post-purification kit to improve the profile results. Each DNA profile was also checked for allele drop-in, indicating low-level mixtures or contamination.

The focus of this research was to determine whether an overall gun swabbing strategy or an individual area swabbing strategy would produce better DNA profile results. The goal was to discern which one was better in an effort to decrease DNA backlogs by eliminating the large number of samples submitted per case. Upon analyzing all data, it was found that the most efficient collection method was to swab an individual location as opposed to taking an overall gun swab. Both the overall and individual area swabs were capable of producing full profiles; however, the overall gun swabs had a greater chance for allele drop-in and mixtures with a minor contributor when their electropherograms were examined. For the revolvers, the best collection location (average DNA yields >0.01ng/µL, least allele/locus drop-out) was the grip. The semi-automatic pistols' best locations for collection (average DNA yields >0.01ng/µL, least allele/locus drop-out) were the grip and front sight blade. Collections from the backstrap area of both types of hand guns also often yielded substantial quantities of DNA. The magazines of the semi-automatic pistols were good collection areas as well. The triggers of each of the firearms were generally poor targets for swabbing, with low average DNA yields (average DNA yields <0.01ng/µL).

DNA, Firearms, Collection

B14 Secondary or Tertiary Transfer Semen DNA Stains?

Ka-Man Pun, Polizia Cantonale - Scientifica, via Chicherio 20, Bellinzona, Ticino 6500, SWITZERLAND; Giuliana Grimoldi, MSc, Polizia Cantonale - Scientifica, via Chicherio 20, Bellinzona 6500, SWITZERLAND; Gianfranco Foglia, via ferriere, Giubiasco, SWITZERLAND; Ilaria Monico, MS, Police Canton Ticino - Forensic Science Unit, via Chicherio 20, Bellinzona 6500, SWITZERLAND; and Emilio Scossa Baggi, via ferriere, Giubiasco, SWITZERLAND*

After attending this presentation, attendees will better understand: (1) interpreting DNA evidence; (2) the study of transfer and persistence parameters according to a suspect's declarations; and, (3) the evaluation of potential tertiary transfer.

This presentation will impact the forensic science community by the power of accurately interpreting DNA evidence in solving criminal cases.

In sexual assault cases, semen stains can often be found on bodies and/or clothing. The goal of this presentation is to show how an accurate interpretation of DNA profiles can assist investigators in solving a rape case.

The case involved a young victim (V) and two male assailants (A1 and A2). Two men met a drunken woman in a park and engaged in sexual vaginal activity with her. Some hours later, the woman woke up semi-nude in an unknown apartment and called the police. No washing actions (i.e., a shower) were taken between the incident and the collection of the forensic samples from their bodies.

Both men admitted having only one act of sexual intercourse with the woman in the park (first A1 and then A2), but said she consented to the act. Since the woman fell asleep abruptly and they did not know her address, they decided to drive to their apartment. They had no intention of having other sexual activity with the woman; they only wished to help her.

Genetic analysis generated several DNA profiles. By comparison to the reference profiles of A1, A2, and V, the source of the alleles detected in the evidence samples was established. Due to the rough nature of the incident, the victim was bleeding. Several bloodstains mixed with the assailants' semen were found on their clothing and inside the car.

DNA analysis and blood and semen testing indicated the following: (1) vaginal samples contained mixed DNA profiles from V, A1, and A2 (semen and blood positive results); (2) penis and testicle samples from A1 contained mixed DNA profiles from V, A1, and A2 (semen and blood positive results); (3) penis and testicle samples from A2 contained single DNA profiles from A2 (semen positive results).

Given the mixed DNA profiles detected from A1 and considering the suspects' denial of any homosexual relationship between them, the final forensic report discussed the possibility of a secondary transfer of A2 semen following this schema: A2 penis1 victim vagina1 A1 penis. A1 denied having a second act of sexual intercourse with the victim, which would explain the presence of A2's semen on his penis. Rather, A1 described digitally penetrating the victim's vagina inside the car. After doing this, he probably touched his penis, thereby contaminating it with DNA from A2. This kind of scenario involved a tertiary transfer: A2 penis1 victim vagina1 A1 fingers1 A1 penis.

Therefore, A1's fingernail swabs were analyzed and found to have mixed DNA profiles composed of the victim's blood and his own DNA. A2's DNA was not present. When these genetic findings did not support his tertiary transfer hypothesis, A1 tried to justify once again this absence of evidence by a simple hand washing. Consequently, the attention focused on the persistence of semen under the fingernails after an act of digital penetration. It was known that hand washing could have a significant effect on the persistence of trace evidence (trace DNA, fibers, gunshot residues, etc.), but what about the semen? Early forensic papers studied persistence of DNA from laundered semen stains showing the robustness of this kind of biological fluid. Despite this lack of published research in this area, it was possible to assess the evidentiary value of these findings by considering the DNA concentration in spermatic and hematic fluids. In an equal volume, there is more DNA in semen than blood. Therefore, it is very difficult or impossible that a simple hand washing would eliminate the semen while leaving the blood.

Semen DNA Stains, Interpretation, Indirect Transfer

B15 Differentiation of Commercial Ammunition Sources of Unburned and Corresponding Burned Smokeless Powders Based on Chemical Composition Using Mass Spectrometry (MS) and Principal Component Analysis (PCA)

Kristen L. Reese, BA, 5228 Madison Avenue, Apt C7, Okemos, MI 48864; A. Daniel Jones, PhD, 219 Biochemistry, East Lansing, MI 48824; and Ruth Waddell Smith, PhD, Michigan State University, School of Criminal Justice, 560 Baker Hall, East Lansing, MI 48824*

After attending this presentation, attendees will understand the chemical composition differences between unburned and corresponding burned smokeless powders. Attendees will learn how PCA can distinguish commercial ammunitions based on chemical composition.

This presentation will impact the forensic science community by demonstrating the effects of burning on the chemical composition of smokeless powders and the potential of PCA for associating and differentiating powders based on differences in chemical composition.

Smokeless powders are the propellant in firearms. Different organic additives are added to explosive materials to enhance powder performance. Examples are stabilizers including Diphenylamine (DPA) and Ethyl Centralite (EC) and plasticizers including Dibutyl Phthalate (DBP) and Dinitrotoluene (DNT). These organic additives can be analyzed by gas or liquid chromatography coupled to MS. Previous research has shown that differences in abundances of organic additives can distinguish ammunition brands. Masses of fragment ions aid in constituent identification, but targeted Tandem Mass Spectrometry (MS/MS) methods are usually limited by user-defined precursor ions which may preclude detection of novel or unanticipated compounds.

Previous studies investigated changes in powder composition before and after firing. Quantities of Volatile Organic Compounds (VOCs) were analyzed from spent cartridges using headspace extraction methods. Samples were collected at various post-firing time intervals, and VOCs were identified or quantified. No correlation was observed between the quantities of unburned organic additives and VOCs. PCA was only performed on VOCs from fired cartridges, not on corresponding unburned organic compounds. The uncombusted residue within cartridges provides a potential source of organics. As typical collection materials, including swabs, present matrix interferences, a direct solvent extraction from cartridges was reported; however, no comparison to the unburned counterpart was described.

The objectives in this research were two-fold: (1) to investigate differences in organic additives present in a variety of powders, including those more than 15 years old; and, (2) to investigate the composition changes that occur post-firing. A variety of ammunition types and calibers were collected. Five cartridges from each box were selected and unburned powders removed from each. Acetone and dichloromethane were used to extract the organic additives for analysis. Five cartridges from each ammunition type were also fired and collected. A direct solvent extraction was used to recover the burned residue from each cartridge.

All extracts were analyzed by liquid chromatography-high resolution MS. Separated compounds were ionized using Atmospheric Chemical Ionization (APCI) in positive and negative mode with multiplexed non-mass selective Collision-Induced Dissociation (multiplexed-CID) coupled with a time-of-flight mass analyzer for accurate mass data. CID was performed at five collision energies, ranging from 10eV to 80eV, applied between the mass spectrometer ion source and mass analyzer. At each collision energy, fragmentation occurs to different extents. Molecular ions at low collision voltages provide information about the molecular mass of the intact compound. Fragment ions, increasingly prominent at higher collision energies, provide structural information. Structural determination was supported by comparison to relevant standards or published spectra, when available. This non-targeted, comprehensive approach has potential for structural determination of unknown compounds with no available standards.

Chromatograms of each extract were pretreated via background subtraction, retention time alignment, normalization, and scaling. Pretreatment was necessary to minimize contributions of non-sample signals on subsequent data analysis. Using PCA, successful association and discrimination of unburned powders according to the original ammunition was achieved. Notably, powders from different commercial ammunitions contained similar chemical compositions, suggesting the same origin. The first two Principal Components (PC1 and PC2, respectively) accounted for 50% of the data set variance in the data set. Powders from the same ammunition closely clustered, while powders from different ammunition separated in the scores plots. PC1 and PC2 differentiated powders based on differences in abundances of EC and akardite II, respectively. Further differentiation was possible with subsequent PCs influenced by DBP, DPA, and nitroso-DPA.

Chromatograms of burned and unburned powder extracts were compared to assess chemical composition differences. The organic additives in burned powders had reduced abundance, with a depletion of DPA greater than the other additives present. The first three PCs accounted for 47% of the variance, with EC, DPA, and akardite II being most influential. Powders from the same ammunition did not associate as closely due to irreproducibility in the burning process. Powders with considerable chemical differences could be sufficiently discriminated.

Smokeless Powders, LC/MS, PCA

B16 *In Vitro* Experiments Using Human Cadaver Head Hairs to Investigate the Formation Mechanism of Postmortem Hair Root Bands (PMRBs)

Jamie N. Fleming, BS, FBI Laboratory, 2501 Investigation Parkway, Quantico, VA 22135; Hilda S. Castillo, PhD, 4401 Roland Avenue, Unit 107, Baltimore, MD 21210; Ernest J. Drummond, MS, 1220 Blair Mill Road, Apt 209, Silver Spring, MD 20910; Rabih Jabbour, US Army Edgewood Chemical Biological Center, APG, MD 21010; Samir Deshpande, 111 Bata Boulevard, Ste C, Belcamp, MD 21017; Dawnie W. Steadman, PhD, University of Tennessee, Dept of Anthropology, 250 S Stadium Hall, Knoxville, TN 37996; Lee Meadows Jantz, PhD, University of Tennessee, Dept of Anthropology, 250 S Stadium Hall, Knoxville, TN 37996-0720; Kathleen Hauther, University of Tennessee, 250 S Stadium Hall, Knoxville, TN 37920; Jack Hietpas, PhD, FBI-ORISE, 2501 Investigation Parkway, Quantico, VA 22135; Stephen D. Shaw, MS, FBI Laboratory, 2501 Investigation Parkway, Quantico, VA 22135; JoAnn Buscaglia, PhD, FBI Laboratory, CFSRU, 2501 Investigation Parkway, Quantico, VA 22135; Brian Eckenrode, PhD, 2501 Investigation Parkway, Quantico, VA 22135; and Joseph Donfack, PhD, 2501 Investigation Parkway, Quantico, VA 22135*

After attending this presentation, attendees will have a better understanding of the biochemical process of hair decomposition and the formation of PMRBs. PMRB is one form of decompositional change presenting as a banded area observed at the proximal end of the root of anagen and early catagen-phase hairs derived from cadavers.[1-5] It has been demonstrated that these banded areas are gas pockets, as they appear dark in transmitted light microscopy and bright in reflected light microscopy.[1] Although the microscopic characteristics of PMRBs have previously been well investigated, the mechanism for their formation requires further research.[1-5]

This presentation will impact the forensic science community by contributing to the understanding of the potential biochemical mechanism(s) of PMRB formation, the chemical species that may be involved, and the protein composition of both banded and non-banded hairs.

Anagen-phase human head hairs were collected from deceased donors of known postmortem interval at the University of Tennessee, Knoxville Anthropology Research Facility. To determine the conditions under which decomposition was promoted or inhibited, non-banded postmortem hairs were trimmed to approximately 1cm in length from the proximal end and immersed in various solutions for 24 days. A visual qualitative assessment of decomposition was performed for each hair at 100x magnification using transmitted light microscopy, before and after immersion. A hair with no visible signs of decomposition was defined as stage 0 in accordance with Koch et al.; stages 1 and 2 refer to slight and full PMRBs, respectively.4

The results from this study support previous findings, indicating that some characteristics of decomposition can be produced when antemortem anagen-phase hairs are submitted to a variety of controlled and uncontrolled (*in vitro*) environmental conditions.[5-10] Of particular note, an ammonium acetate solution (100mM, pH7.0) was found to accelerate the decomposition process of postmortem anagen head hairs (stage 2), and a sodium azide solution (100mM, pH7.5) and protease inhibitor cocktail (3X, pH3.0) exhibited a suppressing effect on hair decomposition (stages 0 and 1), possibly by inhibiting bacterial growth and slowing down protease activities, respectively.[5]

In addition, the protein composition of banded and non-banded postmortem hairs was characterized using liquid chromatography/tandem mass spectrometry. Preliminary qualitative analysis of protein profiles derived from a pool of 20 hairs with stage 2 bands and 20 hairs without bands reveal that fewer proteins are identified in the banded hairs compared to the non-banded hairs. As expected, the majority of the proteins identified are keratin proteins and keratin-associated proteins. It is worth highlighting that no peptidases were identified among the proteins present in the non-banded hair sample group, unlike the banded hair sample group. Overall, these results suggest that peptidases may play a role in PMRB formation through the digestion of proteins and may result in the production of gases that become entrapped between the hair macrofibers.

Forensic, Hair Decomposition, Postmortem Hair Root Bands

B17 Forensic Soil Analysis by Morphologically Directed Raman Spectroscopy (MDRS)

Andrew C. Koutrakos, MS, 29 Murray Avenue, Shelton, CT 06484; and Brooke W. Kammrath, PhD*, University of New Haven, Forensic Science Dept, 300 Boston Post Road, West Haven, CT 06516*

After attending this presentation, attendees will understand the advantages of using MDRS in the identification of the mineral components present in recovered soil samples. In addition, attendees will better understand how MDRS works and the benefits it can provide the forensic community.

This presentation will impact the forensic science community by demonstrating how MDRS can be used to obtain particle distribution and shape information as well as chemical identifications of minerals in soil samples in order to provide an objective and robust method for their comparison and characterization.

Forensic soil examination is often considered to be very complicated because of the complexity of soil, but such diversity and complexity can be useful as it allows for the differentiation of soil samples with high discriminating power. The complex nature of soil minerals provides a means for its characterization, classification, and comparison.

MDRS combines automated particle imaging and Raman spectroscopy in one instrument. Particle imaging is performed to determine particle size and shape distributions of components in a mixture. Raman spectroscopy is useful for determining molecular chemistry because it is rapid, reliable, does not require contact with the sample, and is non-destructive. Combining these two analytical techniques allows the individual components present within a mixture to be independently characterized and compared. Such a tool can be used to gain a better understanding of mixtures across many areas of forensic science, as it is applicable to a range of Raman active samples. This presentation demonstrates the application of MDRS to soil evidence.

The benefits of MDRS for forensic soil analysis are that not only are you able to non-destructively identify the types of mineral specimens in the soil sample by Raman spectroscopy, but you are also able to obtain morphological information about the individual mineral grains, particle size distributions for the entire sample as well as each of the minerals, and quantitative information on the relative number of each of the particles.

In this research, soil samples were collected from four sites along one road in Connecticut and mineral portions were separated by sieving and washing. The results showed that the morphologies of the mineral fractions were the same, as expected since they were collected along the same road. Prior research has shown that the morphology of quartz can be used to differentiate different mineral environments, which could be exploited with MDRS. Additionally, the particle size distributions of some minerals showed significant differences that can be used to distinguish between samples. Furthermore, the particle counts for each mineral were used for a quantitative comparison between soil samples. This revealed differences between the soil samples. Principal Component Analysis (PCA) was used for exploratory analysis to reveal patterns in the data. In three PCs, good separation was achieved between the four data sets, thus indicating the mineral counts achieved by MDRS can be used for sample discrimination.

In conclusion, MDRS has the potential to be a valuable tool for forensic soil analysis because it is a non-destructive, relatively fast, and automated way to collect particle morphology and chemical information.

Soil Analysis, Morphologically Directed Raman, Raman Spectroscopy

B18 Postmortem Identification From Physiological Biometrics: A Study of Fingerprints, Irises, and Facial Images

Tiffany B. Saul, MS, University of Tennessee, Dept of Anthropology, 250 S Stadium Hall, Knoxville, TN 37996; Kelly Sauerwein, MA*, University of Tennessee, Dept of Anthropology, 250 S Stadium Hall, Knoxville, TN 37996; Dawnie W. Steadman, PhD, University of Tennessee, Dept of Anthropology, 250 S Stadium Hall, Knoxville, TN 37996; and Chris Boehnen, PhD, Oak Ridge National Laboratory, PO Box 2008 MS-6075, Oak Ridge, TN 37831*

After attending this presentation, attendees will understand the use of postmortem fingerprint, iris, and facial biometrics for positive identification of unknown individuals, including the maximum number of days each biometric type can be successfully used for identification and how the decomposition processes of human remains affect the utility of biometrics over time.

This presentation will impact the forensic science community by describing the advantages and limitations of these biometrics based upon the points of similarity and match scores for each identifier type.

Biometrics are measurable unique characteristics that are used to classify both living and deceased individuals. This study examines the effects of decomposition on the ability to correctly identify, or match, individuals over time using three physiological characteristics: fingerprints, facial photographs, and iris scans. This study examines the maximum number of days in which usable biometric data can be successfully matched to an individual using digital technologies and how the image quality and ability to obtain sufficient match scores to make a positive identification decreases over time. For the purposes of this study, *usable data* refers to images that are able to correctly identify the individual through a digital biometric program that uses statistical algorithms to match the captured images with those images taken on the initial receipt of the donated individual. This study was conducted in conjunction with Oak Ridge National Laboratory and the University of Tennessee Anthropological Research Facility between April 2014 and January 2015. Digital facial photographs (n=172), iris scans (n=123), and fingerprints (n=480) from the donated remains of thirteen (n=13) individuals were obtained daily until usable data could no longer be captured. The individuals were placed supine and mostly uncovered with the exception of wire or plastic mesh placed over the hands to prevent scavenger activity. The left iris of all individuals was hydrated with 0.4mL of sterile saline solution ten minutes prior to iris scanning to determine if this would increase the quality of images compared to the untreated right iris. No other preparations were made to the remains prior to data collection.

With daily high temperatures ranging between 59°F (15°C) and 84°F (28.89°C) during the spring trial (n=4), usable data was obtained for an average of four days; however, the early summer trial (n=5) included high temperatures between 81°F (27.22°C) and 91°F (32.77°C) and the number of days usable data could be captured was reduced to two. The winter trial (n=4) only had high temperatures between 18°F (-7.78°C) and 55°F (12.78°C) and demonstrated that useable data was available, on average, for 28 days with both facial images and fingerprints persisting over the longest period at 40.75 days and 24.5 days on average, respectively. Overall, fingerprints produced the most reliable biometric data, with more usable data and higher match scores over longer periods of time than iris scans or facial images. Color change, structural changes to facial features due to bloating, and insect activity prohibited the capture of usable facial images after an average of two days in the spring and summer, while dehydration, clouding, and collapse of the cornea prevented capture of usable iris scans after an average of two days in the spring and only one day in the summer. While the winter trial produced more usable images and significantly higher match scores over a longer period of time, scavenging and freezing temperatures limited the quality and quantity of available data.

This study demonstrated that digitally captured fingerprint biometric data can be used up to 25 days postmortem to identify individuals. The results of this study show that biometrics do remain viable over time, depending upon seasonality and environmental conditions. When scavenger activity is inhibited, fingerprints persist longer than facial and iris identifiers; however, temperature, precipitation, and insect activity were the primary factors affecting the retention of biometric information in decomposing human remains. This study builds upon previous work and continues to support the utility of physiological biometric identifiers during the decomposition process. Postmortem biometric research has the potential to make important contributions to forensic anthropology and the law enforcement, military, and medicolegal communities.

Biometrics, Human Decomposition, Positive Identification

B19 Stability Study of Heroin in Four Common Solvents

Melanie A. Schade, 443 Daniel Street, Allentown, PA 18104; and Thomas A. Brettell, PhD, Cedar Crest College, 100 College Drive, Allentown, PA 18104*

After attending this presentation, attendees will have a better understanding of the stability of heroin in common solvents.

This presentation will impact the forensic science community by providing information about the stability of heroin in common solvents and recommending the best storage conditions for heroin samples and standards in these solvents.

The stability of heroin in four different solvents (acetonitrile, chloroform, methanol, and a 1:9 mixture of methanol:chloroform) was studied. The degradation of heroin in the different solvents under various storage conditions was monitored for 13 weeks. Samples of heroin (100ug/mL) in the four solvents were stored at different conditions, including at room temperature (25°C, +/-3°C), in the refrigerator (7°C, +/-3.0°C), in the freezer (-8°C, +/-3.0°C), and on the autosampler of a gas chromatograph (26°C, +/-3°C). The samples were analyzed in triplicate over a 13-week period using Gas Chromatography/Mass Spectrometry (GC/MS). GC/MS was performed using an Agilent® 7890B gas chromatograph interfaced with an Agilent® 5877A mass spectrometer and an Agilent® 7693 autosampler. The column used was a 30m x 0.25mm x 0.25µm HP-5MS UI. Helium was used as the carrier gas with a flow of 1.0mL/min and linear gas velocity set at 38cm/sec. The inlet, detector, and auxiliary temperatures were 250ºC. The mass scan range was set at 40m/z-500m/z for all samples.

Methanol experiments were repeated and confirmed by GC/MS on a Hewlett Packard 5890 gas chromatograph, GC/MS Agilent® Technologies 6890N Network GC System/5973 Network Mass Selective Detector. The column used was a 30m x 0.25mm x 0.25µm Rxi®5Sil MS. The helium carrier gas flow and linear velocity, temperature settings for column inlet, detector, and auxiliary as well as the mass range were the same as above. The column temperature program was optimized for both columns to ensure baseline resolution of heroin and 6-Monoacetylmorphine (6-MAM). The initial column temperature was 130ºC with a hold time of 2.0 minutes, then the oven temperature was increased @15ºC/min to 250ºC without a hold time and increased again @15ºC/min to 320ºC with a final hold time of 3.0 minutes. 1-µL injections of samples were performed in split mode and with a 50:1 split ratio.

Relative concentration ratios of the degradation products to the heroin concentrations were measured semi-quantitatively using the ratio of area counts of the respective chromatographic peaks. Degradation products were identified through spectral analysis and comparison to known certified standards. It was found that heroin breaks down into 6-MAM in methanol. No breakdown products were observed in acetonitrile, chloroform, or the 1:9 mixture of methanol:chloroform at any of the storage conditions. The percent concentration of heroin in methanol decreased as the temperature of the storage condition increased. For the most part, no breakdown was observed for the heroin in methanol stored in the freezer (-8°C, +/-3.0°C). The methanolic samples stored on the autosampler (26°C, +/-3°C) and at room temperature (25°C, +/-3°C) had the greatest decomposition rate with the lowest percent heroin concentrations and respective highest 6-MAM concentrations. The samples stored in the refrigerator (7°C, +/-3.0°C) had higher percent heroin concentrations than the samples stored at room temperature and on the autosampler of the gas chromatograph. Heroin samples stored in methanol at room temperature were degraded by 10% within a few days and totally degraded in 12 weeks. Based on these results, heroin should not be stored in methanol.

Heroin, Diacetylmorphine, GC/MS

B20 The Utility of Ultra High-Performance Supercritical Fluid Chromatography (UHPSFC) for the Chiral Analysis of Seized Drugs

Stephanie R. Breitenbach, BS, 165 Cross Point Drive, Owings, MD 20736; and Ira S. Lurie, PhD, George Washington University, Dept of Forensic Science, 2100 Foxhall Road, NW, Somers Hall, Lower Level, Washington, DC 20007*

After attending this presentation, attendees will understand the use of UHPSFC for chiral separations. This presentation will also explore the chiral mechanism for UHPSFC.

This presentation will impact the forensic science community by presenting separation conditions for the Supercritical Fluid Chromatography (SFC) chiral separation of certain controlled and non-controlled substances; this can help determine the difference between controlled versus non-controlled drugs, as well as impact trial sentencing and law enforcement intelligence.

The recently introduced separation technique UHPSFC produces highly efficient and rapid separations performed on a new generation of analytical SFC instruments with an environmentally friendly mobile phase, containing as the major component carbon dioxide. Carbon dioxide in the supercritical and subcritical state has properties that are intermediate between a liquid and a gas, giving it excellent diffusivity while maintaining liquid-like properties. UHPSFC, like high-performance liquid chromatography and ultra high-performance liquid chromatography, is advantageous for drugs that are thermally labile, polar and non-volatile, solutes that are problematic for Gas Chromatography (GC) analysis. UHPSFC offers increased selectivity for very similar compounds, such as enantiomers; due to interactions with the stationary phase such as hydrogen bonding, dipole and pi-pi interactions, and a steric fit into a chiral surface. In this vein, UHPSFC is amenable to the chiral separation of drugs of forensic interest.

This project will highlight the use of three chiral columns, the AMY1, CEL1, and CEL2 which contain amylose and cellulose respectively as the chiral backbone. These columns were studied for the chiral separation of synthetic cannabinoids, bath salts, and phenethylamines, including methamphetamine. The studies were performed using carbon dioxide (CO2) with several different modifiers and additives. The modifiers include methanol, acetonitrile, ethanol, and isopropanol, while the additives include ammonium formate and ammonia. The synthetic cannabinoids studied consisted of four controlled drugs, including CP 47, 497, its diastereomer epi-CP 47, 497 and their C8 homologues, as well as two non-controlled positional isomers of controlled JWH-018. The "bath salts" investigated included 14 controlled drugs, in addition to seven non-controlled positional isomers of controlled pentedrone and 4-methylcathinone, four non-controlled positional isomers of controlled mephedrone and buphedrone, three non-controlled positional isomers of controlled α-PVP, two non-controlled positional isomers of controlled 4-MEPP and α-PBP, one non-controlled positional isomer for controlled methcathinone, methylone, butylone, pentylone, and MDPV, respectively. The phenethylamines studied included amphetamine, methamphetamine, MDA, MDMA, and MDEA.

The use of UHPSFC enabled the baseline separation of all of the studied enantiomers of synthetic cannabinoids, and dl-methamphetamine. UHPSFC resolved 9 out of 14 enantiomers of the controlled "bath salts", all 21 of the non-controlled positional isomers of the latter solutes, and MDMA with a resolution of 1 or better.

This project was supported in part by the National Institute of Justice, Office of Justice Programs, and United States Department of Justice. The opinions, findings, and conclusions or recommendations expressed in this publication are those of the authors and do not necessarily reflect those of the Department of Justice.

Chiral, Seized Drugs, Supercritical Fluid

B21 Analysis of Black Electrical Tapes by Direct Thermal Extraction-Gas Chromatography/Mass Spectrometry (TE-GC/MS)

Emily Prisaznik, BS, Cedar Crest College, 100 College Drive, Allentown, PA 18104; and Thomas A. Brettell, PhD, Cedar Crest College, 100 College Drive, Allentown, PA 18104*

After attending this presentation, attendees will have a better understanding of how TE-GC/MS can be used to analyze volatiles thermally extracted from electrical tapes.

This presentation will impact the forensic science community by providing an alternative method to analyze and compare electrical tapes that may be submitted as trace evidence to crime laboratories.

Black Polyvinyl Chloride (PVC) electrical tape is often used in the construction of Improvised Explosive Devices (IEDs) as a means of securing their components. Consequently, black electrical tape is often submitted as evidence to crime laboratories. IEDs often incorporate PVC tape for sealing, insulating, or securing parts to the device; therefore, important information can be gained from the analysis of the components of IEDs, either intact or fragmented. Most of the methods that have been developed for the forensic analysis of black electrical tape have used a combination of microscopy, Infrared (IR) and/or Raman spectroscopy, Scanning Electron Microscopy/Energy Dispersive Spectroscopy (SEM/EDS), or Pyrolysis Gas Chromatography (PyGC). New alternative methods to compare and differentiate black electrical tapes are needed.

For this reason, Direct Thermal Extraction-Gas Chromatography/Mass Spectrometry (DTE-GC/MS) was explored as an analysis technique for black electrical tapes. Thermal sampling techniques generally require no sample preparation and can replace more complex and time consuming analytical procedures such as solvent extraction. DTE is a thermal desorption method used to extract Volatile Organic Compounds (VOCs) and semivolatile compounds directly to the gas chromatographic column for analysis. DTE-GC/MS can differentiate and identify volatiles thermally extracted off of polymers such as PVC tapes. This thermal extraction technique is a dynamic process that can be used to analyze both solid and liquid samples. Under a continuous flow of inert gas and heat, volatile and semi-volatile organics are thermally extracted from the sample matrix into the gas stream and transferred to the vapor phase and then into the carrier gas of a gas chromatograph. DTE-GC/MS was used in this experiment to examine black electrical PVC tape samples purchased from various commercial sources. DTE was performed using an SIS AutoDesorb™ system. The AutoDesorb™ tower, containing the sample analysis hardware, sits over the gas chromatographic injection port and communicates with the PC software through the electronics console. Trace amounts (<30mg) of samples were thermally desorbed at 150°C with a purge and flow of helium gas for one minute. Desorption time for all samples was set to ten minutes with an initial column trap temperature at 30°C to focus the volatiles onto the gas chromatographic column.

GC was performed using a 5890 Agilent® gas chromatogaph. A Zebron™ ZB-5HT capillary column (30m+5m Guardian x .25mm i.d. x .10µm) was used for all analyses. A helium carrier gas with a flow rate of 1.0mL/min was used with a 10:1 split. The injector temperature was set to 225°C. The initial column temperature was held at 30°C for two minutes, followed by its first ramp to 150°C increasing 10°C/minute. The second ramp was to 240°C increasing 2°C/minute, finishing with a final ramp to 280°C increasing 10°C/minute. The oven was held at 280°C for five minutes. A post-run program returned the oven temperature to 30°C and lasted ten minutes. MS was carried out on a 5973 Agilent® Mass Selective Detector with a scan range of 40m/z-500m/z and auxiliary temperature of 250°C.

All the black electrical tapes studied produced different chromatograms with peaks of varied intensity. All samples were run in triplicate with excellent reproducibility. The compounds identified originated from volatiles thermally extracted from the tape film and adhesive. Phthalate plasticizers from the tape film were among these peaks. In conclusion, this study provides an innovative and semi-destructive technique to examine trace amounts of polymeric materials, specifically PVC electrical tape that may be submitted to crime laboratories.

Electrical Tape, Direct Thermal Extraction, GC/MS

B22 Think Outside the Box: External Human Factors on the Analysis, Comparison, Evaluation-Verification (ACE-V) Methodology

Francisco Valente Gonçalves, MSc, University of Leicester, Dept of Criminology, 154 Upper New Walk, Leicester LE1 7QA, UNITED KINGDOM; Lisa L. Smith, PhD, University of Leicester, 154 Upper New Walk, Leicester LE1 7QA, UNITED KINGDOM; and Doug Barrett, PhD, University of Leicester, Henry Welcome Bldg, School of Psychology, Leicester, UNITED KINGDOM*

After attending this presentation, attendees will gain a different perspective on the topic of cognitive bias within forensic sciences, namely fingerprint examinations. The goal of this presentation is to suggest some external variables which have not been researched to date and which can contribute to the increase or decrease of latent print examiners' performance during their workflow.

This presentation will impact the forensic science community by providing a different way to observe cognitive contaminations by focusing on external variables such as feedback, accreditation, opportunities for funding, and external pressures from other professionals. In this way, this study looks for the responsibility of other professional roles within the legal system (managers, external consultants, lawyers, and judges) in regard to the topic of miscarriages of justice.

In 2004, in the Madrid bombing case, Federal Bureau of Investigation (FBI) latent print examiners identified Brandon Mayfield as the contributor of a fingerprint associated with the terrorist attack due to a misguided decision within the fingerprint analysis. Research conducted on human factors since that event showed that one possible explanation for the error made by the latent print experts was contextual bias; however, this was not specific to only this case within a forensics laboratory in the United States nor even specific to a particular forensic discipline.

In recent years, the forensic community has found, in a diversity of cases, various flaws in their procedures which have led to miscarriages of justice within the legal system and have required laboratories to reanalyze cases where errors may have occurred.

Due to these incidents, the academic community has contributed research providing governmental institutions with empirical data on human factors and contributing to official reports regarding quality procedures to circumvent issues such as cognitive contaminations.

It has been noted that forensic laboratories around the world have now started to embrace quality and accreditation standards. There is an increased need to seek high levels of quality within the procedures that practitioners undertake in the various disciplines of forensic science during their everyday work flow.

Although there is already research on human factors, this presentation suggests that the majority of the observed variables are associated with what might be called "internal variables," since these are concerned with factors regarding personal characteristics of the latent print examiners (e.g., fatigue, stress, stereotypes, and cognitive contaminations in general).

Thus this study was interested in discussing the plausibility of looking for "external variables" such as feedback from managers, accreditation agencies, and external consultants which can lead to overconfidence, opportunities for funding which enables the laboratory to improve its methodology, equipment, and human resources, and also external pressures from investigators and other departments of investigation, lawyers, or even judges which can lead to contextual bias. These external pressures are believed to be the source of increasing or decreasing motivation within examiners' work flows which affects their performance.

By investigating the impact these variables have on forensic practitioners' performances, other roles of the legal system will be included in this discussion as well as how to achieve a more holistic understanding of the causes of error and how to manage these risks to avoid future miscarriages of justice.

With strong collaborations between different institutions (e.g., forensic laboratories, departments of investigations, courts, and accreditation agencies), it is possible to improve quality assurance and quality control for forensic procedures, thus improving the legal system overall.

Fingerprints, Errors, Standards

B23 Liquid Chromatography/Mass Spectrometry (LC/MS) Method Development for the Identification of Route-Specific 3,4-Methylenedioxymethamphetamine (MDMA) Impurities

Rebecca F. Dunn, 885 N Easton Road, Apt 3A6, Glenside, PA 19038; and Heather L. Harris, MFS, JD, PO Box 43626, Philadelphia, PA 19106*

After attending this presentation, attendees will better understand the benefits of using LC/MS instrumentation over Gas Chromatography/Mass Spectrometry (GC/MS) for impurity profiling of amphetamine impurities.

This presentation will impact the forensic science community by demonstrating the simple extraction techniques possible with LC/MS instrumentation.

MDMA is a Schedule 1 psychoactive hallucinogenic stimulant commonly found in "Ecstasy" tablets or referred to as "Molly." By analyzing the organic by-products, or impurities, in MDMA tablets, it is possible to identify the synthetic route used to prepare the sample. Two of the most common methods of synthesis are the reductive amination of MDP-2-P and the Leuckart reaction. The differentiation between these two synthetic routes can aid investigators in the identification of the manufacturer of the sample and help to compare tablets from multiple drug seizures.

In the past decade, several GC/MS techniques have been developed to analyze MDMA tablets and to identify common route-specific impurities. It is hypothesized that LC/MS will be more suitable for this research due to its increased sensitivity and ability to analyze more polar compounds without derivatization. The goal of this research was to develop a simplified method for the extraction and identification of 11 previously identified route-specific MDMA impurities using dry extraction techniques and LC/MS instrumentation. By only identifying the impurities selected, this method is able to focus on the impurities, typically found at low concentrations, which indicate these two popular synthetic routes. In order to achieve this goal, an LC/MS method was designed to identify the compounds and several extraction methods were evaluated for the optimal extraction of the compounds of interest from simulated tablet matrices.

Of the impurities chosen, eight were indicative of the reductive amination route. These compounds were: N-cyclohexylacetamide; 3,4-methylenedioxyamphetamine (MDA); p-methoxymethamphetamine (PMMA); N-(1,3-benzodioxol-5-yl-methyl)-N-methylamine; 3,4-methylenedioxyacetophenone; 3,4-methylenedioxypropiophenone; methyl piperonylate; and 3,4-methylenedioxyethylamphetamine (MDEA). The remaining three were indicative of the Leuckart reaction. These compounds were: N-ethylamphetamine; N-formylmethamphetamine; and N,1,7,7-tetramethylbicyclo-[2.2.1]-heptan-2-amine. In addition to the impurities that were analyzed, the LC/MS method was designed to identify MDMA and caffeine in order to ensure that the presence of the primary ingredient and a popular additive would not inhibit the identification of the analytes of interest. Benzylmethylamine was used as an internal standard.

The LC/MS method developed for the identification of the analytes of interest was able to qualitatively identify all compounds at concentrations above 2µg/mL and identify all amphetamine analytes at concentrations above 1ng/mL. All analytes were positively ionized and baseline separated.

Three dry extraction methods were utilized for the extraction of the compounds of interest from tablets. The compounds of interest were extracted from four different common excipients: cornstarch; d-lactose; d-sorbitol; and microcrystalline cellulose. The extraction solvents were methanol, 0.05 N hydrochloric acid in methanol, and 0.1% trifluoroacetic acid (TFA) in methanol. Percent area ratios were used to determine the percent recovery of each method and these results were compared to the percent recoveries obtained from a previously optimized liquid-liquid extraction method. When extracted from cornstarch, the liquid-liquid extraction had the highest average percent recovery for all compounds at 58%. Of the three dry extraction methods, the methanolic hydrochloric acid had the highest average percent recovery at 52%, with the methanolic TFA having 48% and the methanol having 42%. When the percent recoveries for the individual analytes are compared, the data shows that the methanolic hydrochloric acid was the optimum extraction method for a majority of the analytes, but lower recoveries for MDMA and caffeine drastically reduced the overall average.

Liquid Chromatography, MDMA, Impurity Profiling

B24 Forensic Analysis of Human Autopsy Tissue for the Presence of Polydimethylsiloxane (Silicone) and Volatile Cyclic Siloxanes Using Macro Fourier Transform Infrared (FTIR) Spectroscopy, Micro-FTIR Spectroscopic Imaging, and Headspace/Gas Chromatography With Mass Spectrometric Detection (HS/GC/MS)

Caroline Machal Kelley, BS, USFDA-FCC, 6751 Steger Drive, Cincinnati, OH 45237; and Adam C. Lanzarotta, PhD, USFDA-FCC, 6751 Steger Drive, Cincinnati, OH 45237*

After attending this presentation, attendees will see the advantages of using HS/GC/MS, in addition to those offered by FTIR spectroscopy, to provide complementary data yielding a strong indication for the presence of silicone in human autopsy tissue.

This presentation will impact the forensic science community by showcasing effective and minimally labor-intensive primary FTIR and secondary HS/GC/MS methods for the detection of silicone in human autopsy tissue.

The United States Food and Drug Administration's Forensic Chemistry Center (FCC) has received multiple requests over the past 15 years to examine hypodermic needles, syringes, and unknown liquids for the presence of polydimethylsiloxane (PDMS) (silicone); however, in the past five years, due to the rise in silicone injection popularity including "pumping parties," the FCC has been tasked with analyzing human tissue samples for PDMS. In these cases, PDMS was allegedly injected into patients' lips, face, breasts, buttocks, and/or other areas of the body for cosmetic enhancement by unlicensed individuals. The practice has led to several serious health complications, including death. In the event of a death, the medical examiner often requests that the victim's autopsy tissues be examined for the presence of PDMS in order to help determine the extent to which the PDMS has migrated in the body, which may ultimately help the medical examiner determine the cause of death.

Benefits of FTIR and Raman methods, both point mode and imaging mode, include the ability to provide PDMS-specific, solid-state (morphological), *in situ* examinations of biological tissue inclusions. The disadvantage is that prior to analysis, these studies required the tissue to be rinsed with an organic solvent, cross-sectioned with a microtome, and carefully mounted to an IR-reflective substrate, which is not typically how autopsy tissue samples are received by the FCC. Furthermore, this approach can be unnecessary and prohibitively time consuming for applications that do not require morphological information via an *in situ*, nondestructive approach (i.e., simply answering the question of whether or not PDMS is present in autopsy tissue). As a result, it was of interest to develop a straightforward primary PDMS-specific method using FTIR spectroscopy and/or FTIR spectroscopic imaging for the analysis of human autopsy tissue received directly from the medical examiner with little or no treatment or preparation.

GC/MS was considered as a secondary technique because of the low detection limit and high selectivity/sensitivity of this method for detecting Volatile Cyclic Siloxanes (VCSs). The drawback to this approach is that the GC/MS method required significant sample preparation and the results may yield a broad peak manifold for silicone. On the other hand, HS/GC/MS, which, as far as this study could determine, has not yet been utilized for the determination of VCS impurities as marker compounds for PDMS in human autopsy tissue, offers several advantages compared to conventional GC/MS methods. First, HS/GC/MS requires less sample preparation because the sample can often be analyzed neat. Even if the sample cannot be examined neat due to low VCS concentrations, minimal sample preparation is required; the tissue sample is extracted with hexane and the extract is analyzed. Second, regardless of whether the tissue sample is examined neat or as an extract, the HS/GC/MS analysis yields a cleaner chromatogram because the broad silicone peak observed using GC/MS is not observed in the HS method since PDMS has a much lower vapor pressure than the VCSs and therefore will remain in the tissue sample or extract liquid.

Effective and minimally labor-intensive primary and secondary methods have been developed for the detection of silicone in human autopsy tissue. The primary method is PDMS-specific and employs either macro Attenuated Total Reflection/Fourier Transform Infrared (ATR/FTIR) spectroscopy (for samples with a relatively high PDMS concentration) or micro FTIR spectroscopic imaging in a reflection/absorption modality (for samples with a relatively low PDMS concentration). Although the secondary method is not PDMS-specific, it is a novel approach and employs HS/GC/MS for the detection of VCSs, which are characteristic marker compounds for PDMS.

These techniques and methods have been successfully employed in 11 cases involving the examination of various types of human tissues for the presence of PDMS. To date, the offenders have been found guilty of felonies including third-degree murder, depraved heart murder, and criminally negligent homicide with convictions ranging from several months to life in prison.

Silicone, Human Autopsy Tissue, HS/GC/MS

B25 Breaking Forensic Boundaries: Developing International Standards

Soraya McClung, Houston Forensic Science Center, 1200 Travis Street, 20th Fl, Houston, TX 77046; and Kermit B. Channell II, BS*, Arkansas State Crime Laboratory, #3 Natural Resources Drive, Little Rock, AR 72205*

The goal of this presentation is to provide information about global initiatives whose purposes are to develop international standards for both forensic science providers and for the manufacturing of forensic products.

This presentation will impact the forensic science community by educating attendees on the purpose and objectives of the International Organization for Standardization Technical Committee (ISO/TC) 272. This presentation will include background information on ISO/TC 272, recent achievements, and future projects.

ISO/TC 272 has been established to develop internationally accepted standards relating to the delivery of forensic science services. Such standards primarily apply to organizations that analyze and/or interpret physical evidence for the purposes of presenting conclusions to a court of law. The standards are designed to preserve the features of evidence subject to observation and to maintain the integrity of that evidence through each stage of testing. They are also designed to facilitate information sharing between international jurisdictions.

The quality and nature of the materials, reagents, and consumables used by forensic service providers during testing can negatively impact the features of the physical evidence under examination. As such, the committee also develops standards directed toward manufacturers. These standards are meant to control the production of such materials to ensure they are fit for forensic purposes. The committee recently produced the Final Draft International Standard (FDIS) 18385, "Minimizing the risk of human DNA contamination in products used to collect and analyze biological material for forensic purposes."

In 2009, the National Academy of Sciences (NAS) Report, Strengthening Forensic Science in the United States – A Path Forward, highlighted the lack of forensic standards and the potential impact this was having on the administration of justice. These criticisms are applicable worldwide. A number of countries are now in the process of developing national forensic standards. Standards Australia has published AS5388 Forensic Analysis. Comité Européen de Normalisation (CEN) is currently developing a draft standard for the collection of forensic evidence. There are also a number of American Society for Testing and Materials (ASTM) standards in existence. The continuation of standards being developed in each country without cross-border coordination and collaboration may limit the exchange of forensic evidence and intelligence across international borders. This lack of communication could also negatively impact the investigation of global crime including terrorism, fraud, and child exploitation. This is also creating duplication of effort by ISO member bodies.

The objectives of the TC are to develop standards that: (1) enhance the reliability of forensic evidence; (2) establish consistent work practices that facilitate forensic laboratories/agencies from different jurisdictions to work collaboratively in response to cross-border investigations; (3) enable agencies from different jurisdictions to support one another in the event of a catastrophic event that exhausts a jurisdiction's capabilities; and, (4) allow for the exchange of forensic results, information, and intelligence, including the sharing of databases.

Standards, International, Technical Committee

B26 Human Scent Evidence — Volatile Organic Compounds (VOCs): A Unique Trace From Science to Criminal Investigation

Marcello Rendine, Viale degli Aviatori 1, Foggia 71100, ITALY; Cristoforo Pomara, MD, PhD, University of Foggia, Dept Forensic Path, University of Malta, Dept of Anatomy, Faculty of Med & Surg Biomedical Sci, Foggia, Misida, Malta 71100, ITALY; Alessandro Bellifemina, Viale degli Aviatori 1, Foggia 71100, ITALY; Dania De Carlo, MD, Ospedale Colonnello D'Avanzo, Viale degli Aviatori 1, Foggia 71100, ITALY; Carmela Fiore, MD, Ospedale Colonnello D'Avanzo, Viale degli Aviatori 1, Foggia 71100, ITALY; Palmira Fortarezza, MS, Ospedale Tatarella, Cerignola, ITALY; Margherita Neri, MD, PhD, University of Foggia, Dept of Forensic Pathology, Viale degli Aviatori 1, Foggia 71100, ITALY; and Irene Riezzo, MD, PhD, University of Foggia, Osp D'Avanzo, Dept of Forensic Pathology, Viale degli Aviatori, 1, Foggia 71100, ITALY*

The goal of this presentation is to demonstrate to the forensic science community the specific VOCs from human scent evidence that elicit an appropriate response by properly trained scent-discriminating canines.

This presentation will impact the forensic science community by explaining that the identification of VOCs released by a unique human scent may be useful aids in training scent-discriminating dogs to use in criminal investigations.

Whenever a crime is committed, forensic personnel are requested in order to collect crime scene evidence to establish relationships between suspects and the crime. In the event that physical evidence is destroyed or not found, there is one type of latent evidence that is always deposited at the crime scene: the unique human scent. Although the concept of human scent as forensic trace evidence is not new, there is currently very little understanding of how human scent is produced and of its uniqueness.

Recent increases in the use of trained canines for selectively discriminating human scent has created the need to have an exact knowledge and awareness of the volatile chemical signature of compounds that could indicate the presence of an alleged offender at the crime scene.

The uniqueness of human scent is based on the combination of many factors including diet (primary odor), environmental influences (secondary odor), external sources (tertiary odor), and genetics. Although human scent is defined by the most abundant VOCs, only a few VOCs can become airborne and detected by the canine olfactory system.

This study was performed using Gas Chromatography/Mass Spectrometry (GC/MS) to identify the VOCs released from humans that stimulate canine olfactive discriminating alerts and the indirect scenting system. Scents in this study were collected from eight people (four male and four female). These subjects washed their hands under running water using the same soap and waited for them to dry naturally without contact with any object or person. The experimental subjects then touched some objects (the scent articles) in the same room in order to imprint their odor.

For the indirect scenting system training, the surface of the scent article was wiped with 40 sterile and VOC-free cotton gauze pads; likewise, for a passive absorption, 40 sterile and VOC-free cotton gauze pads were placed on the scent article for 48 hours. These were stored in 80 separate glass jars covered by a sterile, VOC-free film and closed with a lid. The jars were stored at constant room temperature (22°C and 45% relative humidity). The gauze pads were subsequently presented to the canine to sniff and stimulate discriminating alerts.

The gauzes were used in part for the chemical analysis and in part for the dog training procedure. The first extraction was assessed on the gauze as time 0 of the experiment. The headspace extractions were repeated every 5 days for 20 days, resulting in 40 extractions. The National Institute of Standards and Technology (NIST) mass spectral library and extracted ion chromatograms were used to identify the compounds.

During the analysis, more than 50 VOCs were identified. Only VOCs originating from human specimens were used in the analysis of the samples as key markers of the presence of the suspect at the crime scene. The various molecules were selected and analyzed so as to identify and assess their changes according to the experimental subject's unique human scent.

The results of this study indicate that the professionally trained scent identification dog is an outstanding biological device for collecting invisible trace evidence at the scene of crime, displaying excellent sensitivity (between 99.42% and 100%) and specificity (between 99.05% and 100%) and having a Positive Predictive Value (PPV) ranging between 97.94% and 100%, and a Negative Predictive Value (NPV) ranging between 95.71% and 100%.

Human Scent Evidence, Volatile Organic Compounds, CSI Canines

B27 Chemical and Canine Analysis as Complementary Techniques for the Identification of Active Odors in a Biothreat Agent

Alison Simon, BS, 11200 SW 8th Street, CP304, Miami, FL 33199; Julian L. Mendel, MSc, 10005 SW 141 Court, Miami, FL 33186; Kenneth G. Furton, PhD, Florida International University, International Forensic Research Institute, University Park, Miami, FL 33199; and DeEtta Mills, PhD, Florida International University, OE 167, Biological Sciences, 11200 SW 8th Street, Miami, FL 33199*

After attending this presentation, attendees will better understand the biothreat agent *Raffaelea lauricola*, which causes the lethal laurel wilt disease. Attendees will understand how research is combating the spread of this fungus by using a combination of chemical analysis and canine trials to identify the active odors and create a safer, longer-lasting training aid.

This presentation will impact the forensic science community by introducing a novel method of identifying active odors to be used in the field of forensic canines in order to prevent the spread of *R. lauricola* through canine detection. This presentation will also strengthen the validity of canine detection as it is currently used in forensic science.

Canines have served an integral part of forensic science for more than a century, yet there is little science to support their ability to distinguish Volatile Organic Compounds (VOCs) of illegal or controlled substances. By identifying the odors to which canines alert, it is possible to create safer, longer-lasting training aids, as well as provide scientific support in legal proceedings. In the case of the invasive biothreat agent *R. lauricola*, canines are currently the only method of early detection. *R. lauricola* is a fungus that was brought into the country in the early 2000s and is currently devastating avocado groves in the United States. It causes the laurel wilt disease that kills trees within six weeks. The fungus is carried by an invasive beetle (*Xyleborus glabratus*) which bores into a host tree and farms the phytopathogenic fungus as food. The tree attempts to halt the spread of the fungus by systematically shutting down its respiratory system, which unintentionally stops the spread of nutrients and water and kills the tree. Once a biothreat or other banned agricultural item has entered the country, there is no established, uniform method of eradication.

The current study used Solid Phase Microextraction/Gas Chromatography/Mass Spectrometry (SPME/GC/MS) to identify the odors present in avocado trees infected with the pathogen. Twenty-eight compounds were identified using this method; however, most of these compounds were not commercially available. In order to create a training aid for canines trained to detect *R. lauricola*, the compounds the canines are alerting to had to be identified. To this end, two separate canine trials were completed. First, four canines were run on Controlled Odor Mimic Permeation Systems (COMPS) made of infected tree wood, uninfected tree wood, and fungus cultures. All canines successfully alerted to infected tree wood and fungus cultures, but not uninfected tree wood, proving that the canines are alerting to fungal odors present in infected trees with a positive predictive value of 98.3%. The second trial was designed to identify these odors without the assistance of pure compounds, since they are not commercially available. By venting a GC column to the atmosphere, fractions of the chromatograph were collected. These fractions were presented to the canines in a series of trials, resulting in the identification of a portion of chromatogram that the canines alert to as active odors for the biothreat *R. lauricola*. Using the fraction identified by the canines, an environmentally safe and longer-lasting training aid will be created. Additionally, a new method of odor identification was created for future use in the field of forensic canines.

Biothreat, Canine Detection, *Raffaelea Lauricola*

B28 Investigating the Use of New Psychoactive Substances (NPS) Using Sewage-Based Epidemiology (SBE): Detection and Identification of Transformation Products (TPs) of Methylone and Methylenedioxypyrovalerone in Sewage Using Accurate-Mass Mass Spectrometry (MS)

Juliet Kinyua, MSc, Universiteitsplein 1, Berchem, Antwerp 2600, BELGIUM; Noelia Negreira, PhD, University of Antwerp, Universiteitspein 1, Campus Drie Eiken, Wilrijk 2610, BELGIUM; Ann-Kathrin McCall, MSc, Eawag, Swiss Federal Institute of Aquatic Science, CH-8600 Dübendorf, Zurich, SWITZERLAND; Christoph Ort, PhD, Eawag, Swiss Federal Institute of Aquatic Science, CH-8600 Dübendorf, Zurich, SWITZERLAND; Adrian Covaci, PhD, University of Antwerp, Universiteitsplein 1, Antwerp 2610, BELGIUM; and Alexander van Nuijs, PhD, University of Antwerp, Universiteitspein 1, Campus Drie Eiken, Antwerp 2610, BELGIUM*

After attending this presentation, attendees will understand non-target strategies based on Liquid Chromatography (LC) coupled to quadrupole Time-of-Flight/Mass Spectrometry (qTOF/MS) to identify NPS and their in-sewer TPs which are useful in SBE. This presentation demonstrates the elucidation of tentative structures of TPs of two NPS: methylone and methylenedioxypyrovalerone (MDVP).

This presentation will impact the forensic science community by revealing recent developments in SBE for the detection and identification of NPS use. This presentation illustrates potential NPS biomarkers and provides an approach for their identification in sewage.

Introduction: The SBE approach relies on the analysis of excretion products of Illicit Drugs (IDs) in sewage with the purpose of estimating community drug use. It is based on the fact that an ingested dose of ID is metabolized and excreted mostly in urine as parent compound and metabolites ending up in influent sewage. It uses concentrations of ID and metabolites in influent sewage to back-calculate amounts of these substances used by a community. SBE has been applied since 2005 as an approach complementary to classical investigation methods such as medical records, population surveys, and crime statistics for estimating ID use in communities.

While SBE has been applied repeatedly for the estimation of conventional ID use, only a few studies have quantified NPS in sewage. These studies have shown that NPS concentrations in sewage are generally very low. Also, it would be worthwhile to explore the possibility of other biomarkers since parent compounds may be subject to metabolism and transformation during their in-sewer transport.

In this study, the stability of methylone and MDPV in sewage and the possible formation of TPs were studied in the presence of biofilm. The experiments were conducted individually for each selected compound over 24h.

Methods: The LC system consisted of an Agilent® 1290 Infinity LC and separation was performed using a Phenomenex Biphenyl (100 x 2.1mm, 2.6µm) at a flow rate of 0.4mL/min. The mobile phase consisted of: (1) H2O with 0.04% HCOOH; and, (2) 80/20 AcN/H2O with 0.04% HCOOH. The applied gradient, in function of B, was: 0min, 2%; 2min, 2%; 18min, 40%; 25min, 90%; 29min, 90%; 29.5min, 2%; and 33min, 2%. The MS system consisted of an Agilent® 6530 Accurate-Mass qTOF instrument operated with jet stream electrospray ion source. The source parameters were as follows: gas temperature, 325°C; gas flow, 8L/min; nebulizer gas, 40psi; sheath gas temperature, 325°C; sheath gas flow, 11L/min; and capillary voltage, 3,500V and the nozzle voltage, 0V. The data-independent acquisition (All-ions MS/MS) was set up to acquire three scan segments in MS mode alternating the collision energies 0eV, 15eV, and 35eV, respectively. With this acquisition mode, in only one injection, data are acquired in scan segment one to display the "precursor ion" (0eV), and scan segment two and three to provide the product ions (15eV and 35eV).

Samples collected over the 24h period were first centrifuged at 8,000rpm for seven minutes before directly injecting them into the LC/qTOF/MS system.

Results: Results showed that after 24h, MDPV and methylone were not stable compounds, with only 67% and 59% of the initial concentration remaining, respectively. MDPV transformation in the presence of biofilm revealed the formation of three TPs corresponding to the loss of the methylene group (*m/z* 264.1579, C15H21NO3), di-hydroxylation (*m/z* 308.1467, C16H21NO5), and hydroxylation in the pyrrolidine ring, oxidation and ring opening (*m/z* 292.154 (C16H21NO4).

Methylone transformation also revealed formation of three TPs: loss of water by the formation of a conjugated indole system between the primary amine and the aromatic ring (*m/z* 188.0678 (C11H9NO2); reduction of the group ketone (*m/z* 210.1115, C11H15NO3); and loss of the methylenedioxy moiety after formation of the indole system (*m/z* 146.0587, C9H7NO).

This study successfully utilizes data-independent acquisition and non-target data processing techniques in the identification of TPs from MDPV and methylone. These developments in identification of the most suitable biomarker could improve detection of NPS using the SBE approach and serve as an early warning system to stakeholders.

Non-Target Strategies, Sewage-Based Epidemiology, NPS

B29 Updates From the Drug Enforcement Administration National Forensic Laboratory Information System (NFLIS): Opiates and Related Drugs Reported in NFLIS — 2009-2014

DeMia P. Pressley, MS, Drug Enforcement Administration, Office of Diversion Control, 8701 Morrissette Drive, Springfield, VA 22152; Artisha Polk, MS, Drug Enforcement Administration, Office of Diversion Control, 8701 Morrissette Drive, Springfield, VA 22152; Liqun Wong, MS, 8701 Morrissette Drive, Springfield, VA 22152; Kevin Strom, PhD, 3040 Cornwallis Road, Research Triangle Park, NC 27709; Katherine N. Moore, MS, RTI International, 3040 E Cornwallis RD, RTP, NC 27709; David Heller, BS, RTI International, 3040 E Cornwallis Road, RTP, NC 27709; Jeffrey M. Ancheta, BS, 3040 Cornwallis Road, Research Triangle Park, NC 27709; BeLinda J. Weimer, MA, 3040 Cornwallis Road, Research Triangle Park, NC 27709; Hope Smiley-McDonald, PhD, RTI International, 3040 E Cornwallis Road, Research Triangle Park, NC 27709; and Jeri D. Ropero-Miller, PhD, RTI International, 3040 Cornwallis Road, PO Box 12194, Bldg 7, Rm 211, Research Triangle Park, NC 27709*

After attending this presentation, attendees will understand the breadth of information that the NFLIS provides to the forensic community.

This presentation will impact the forensic science community by providing specific knowledge of national and regional trends for opiates and related substances as reported to NFLIS between 2009 and 2014.

The objective of this presentation is to provide the community with a special report on opiates and related drugs reported to NFLIS from 2009 to 2014 and highlight two NFLIS resources, the Data Query System (DQS), and the Drug Information System.

NFLIS is a program of the Drug Enforcement Administration (DEA), Office of Diversion Control that collects drug identification results from cases analyzed by federal, state, and local laboratories. The system currently includes data from laboratories that conduct analyses of more than 91% of the nation's approximately one million annual state and local drug cases. A total of 278 individual laboratories from state systems and local or municipal laboratories/laboratory systems participate in NFLIS. Results from NFLIS are regularly used to support drug scheduling efforts and to aid drug initiatives, including the identification and tracking of emerging drugs of abuse.

Semiannual national estimates from January 2009 to June 2014 are presented for 16 opiates and related substances, as are reports of fentanyl identified with other drugs in the same item. Maps showing state- and county-level reports of oxymorphone, hydromorphone, and fentanyl are also presented. NFLIS results for emerging opiate-related drugs such as mitragynine, acetyl fentanyl, AH-7921, MT-45, and desomorphine are shown. Federal data from DEA and United States Customs and Border Protection laboratories are presented, along with data from IMS Health's™ National Prescription Audit Plus Retail database, the DEA's Automation of Reports and Consolidated Orders System (ARCOS), and Centers for Disease Control and Prevention (CDC) medical examiner data on deaths associated with opiates and related drugs.

From January 2009 to June 2014, an estimated 1,438,933 opiates and related drugs were reported to NFLIS. The number of reports increased by 28% over this period, from 116,647 drug reports during the first half of 2009 to 149,722 during the first half of 2014. From the first half of 2009 to the first half of 2014, hydromorphone reports more than doubled in the South from a rate of 0.75 reports to 2.05 reports per 100,000 persons (679 to 1,965 reports). All other regions fluctuated between minor increases and decreases in hydromorphone reports within the six-month reporting periods. Fentanyl reports increased by 300% from the second half of 2013 to the first half of 2014. This increase was especially pronounced in the South (759 reports), Northeast (711 reports), and Midwest (697 reports). Acetyl fentanyl, AH-7921, and MT-45 were first reported to NFLIS in 2013, whereas mitragynine was first reported in 2010. Acetyl fentanyl increased from 6 reports during the second half of 2013 to 55 reports during the first half of 2014. According to medical examiner data compiled by the CDC, 202,157 deaths were the result of a drug poisoning or overdose between 2009 and 2013. Of these deaths, 57% involved heroin and natural, semisynthetic, and synthetic opiates.

NFLIS publically shares data that can benefit management decisions of crime laboratories through various reports throughout the year, including special reports on such drug classes as presented in this presentation. NFLIS provides a resource for the community to identify and respond to drug trends.

Opiates, Regional Trends, National Estimates

B30 Statistical Analysis of Firearms: A Comparison Between the 2D and 3D Integrated Ballistic Identification System (IBIS®)

Keith B. Morris, PhD, 208 Oglebay Hall, 1600 University Avenue, PO Box 6121, Morgantown, WV 26506-6121; Roger Jefferys, BS*, 27 Dafonzo Hill Road, Pursglove, WV 26546; and Eric F. Law, BS*, 35 Metro Towers Lane, Apt 205, Morgantown, WV 26505*

After attending this presentation, attendees will understand how Bayesian networks can be used to estimate likelihood ratios based upon information available during a specific firearms-related investigation, how to interpret that data in order to obtain the best results for use in a court of law, and how to provide validity for the state and the accused.

This presentation will impact the forensic science community by providing a greater understanding of the means to interpret firearms evidence by using Bayesian networks which were developed from data retrieved from 2D and 3D IBIS®.

IBIS®, developed by Forensic Technology International (FTI), serves as the backbone of the National Integrated Ballistic Information Network (NIBIN) system.[1] This system allows for the databasing of images of cartridge cases and bullets.

The goal of this study was to perform a 3D IBIS® analysis and compare the results to that of a 2D IBIS® analysis. The intra- and inter-variation of the results were also analyzed. A West Virginia University (WVU) Legacy IBIS® and the new 3D FTI IBIS® were used during this study. The cartridge cases from a sample set of 12 9mm firearms were used to study 3D correlations with the cooperation of FTI. These 12 firearms were selected based on preliminary data which displayed their performances of Breechface (BF) and Firing Pin (FP) IBIS® scores via their Receiver Operating Characteristic (ROC) curves and the accompanying Area Under the Curve (AUC) values. ROC curves can be used to determine the crossovers between match and non-match. The ROC curve demonstrates the discriminating power of the method. In other words, it determines how well the method can differentiate between different states of the samples to which the method has been applied. This discriminating ability is directly related to the area under the ROC curve.

A Bayesian network was created to help compare IBIS® scores from the 2D and 3D IBIS® correlations using Netica®, a program for working with belief networks and influence diagrams.[2] Scatter plots, density distributions, and ROC curves were generated for the 2D and 3D data using RStudio®, a user interface for R[3], a computer programming language and environment for statistical computing and graphics.[4]

The worst discriminating power category from FTI with respect to all the firearms analyzed is 2D BF whereas the best discriminating power category is 3D FP. The worst discriminating power category from WVU with respect to all firearms analyzed is coincidentally the BF scores while the best is the FP. Comparing all of the data from both instruments, they behaved similarly, resulting in the worst performance resonating from a Ruger® LC9 in the category of 2D BF scores. Also noteworthy is the benefit of the addition of the side light feature for analyzing the BF. Overall, with regard to an added dimension (i.e., 2D vs. 3D), there was no significance in the results to conclude that one is better than the other.

Firearms, IBIS®, Bayesian

B31 "I Dropped Acid." "No, You Didn't." A Retrospective Study of NBOMe Emergence in Harris County, Texas

Warren C. Samms, PhD, 1885 Old Spanish Trail, Houston, TX 77054; Donna E. Williams, BS, Harris County Institute of Forensic Sciences, 1885 Old Spanish Trail, Houston, TX 77054; and Kay McClain, BS, Harris County Institute of Forensic Sciences, 1885 Old Spanish Trail, Houston, TX 77054*

After attending this presentation, attendees will better understand the growing availability and use of the hallucinogen class NBOMe within the largest county of Texas. These drugs continue to grow in popularity in southeast Texas, despite fatal overdoses reported in Texas and elsewhere in the United States.

This presentation will impact the forensic science community by showcasing a four-year emerging trend of a powerful and deadly class of hallucinogens. The data will show that users appeared not to know the identity or the danger of the substance they possessed. This information will be of use to other communities in helping to address emerging drug trends.

In the early 2010s, many "designer" substances appeared, including synthetic cannabinoids, substituted cathinones, and NBOMe, also known as "New LSD" hallucinogens, such as "25-I," "25-C," and "25-B." The drugs became available inexpensively online and in retail outlets, reaching a young demographic. This, coupled with the high-potency NBOMe compounds, caused a serious public health concern. Some of the first reported deaths from these potent hallucinogens were found in Harris County, Texas.

The Harris County Institute of Forensic Sciences Drug Chemistry Laboratory first encountered NBOMe hallucinogens in January 2012 as part of a large seizure of various stimulant, hallucinogen, and cannabinoid powders. Since then, the number of incoming NBOMe hallucinogens has increased each year: 19 items in 2012, 67 in 2013, and 115 in 2014. It has been identified on blotter paper, in liquid and, on a few occasions, in solid dosage forms. Most commonly, small quantities for personal use are submitted to the laboratory.

Given the increasing number of small-quantity possession cases, despite increasing media attention on the harmful and potentially fatal effects of these drugs, it is hypothesized that many of those people found in possession of NBOMe hallucinogens did not know the identity of the substance and did not understand the risk. It was speculated that suspects often believed that they possessed LSD.

The offense reports of all cases that had tested positive for one of the NBOMe hallucinogens over the period from 2012 to present were examined. Demographic data, the location of the seizure, and suspects' statements regarding the identity of the drug were gathered. These data were correlated with the charging information and the judicial outcome, and charging trends were looked for. As expected, suspects commonly claimed NBOMe was LSD or some other unrelated substance. Very few suspects mentioned "N-bomb," "New LSD," or "NBOMe." These and other details of the study will be discussed.

NBOMe, Designer Drugs, Retrospective

B32 A Study of Microcrystal Tests for Emerging Psychoactive Substances

Sean Brady, West Chester University of PA, West Chester, PA 19383; and Monica Joshi, PhD, West Chester University, Dept of Chemistry, Schmucker Science South, 750 S Church Street, West Chester, PA 19383*

After attending this presentation, attendees will be able to evaluate the role of microcrystal tests in the detection and identification of emerging psychoactive substances.

This presentation will impact the forensic science community by providing a renewed look at microcrystal tests as quick, simple, and effective steps in a drug identification process. This presentation describes the application and chemistry of traditional microcrystal test reagents for the identification of the new classes of psychoactive substances.

Microcrystal tests have held a place in drug identification schemes because they have features of both presumptive tests and confirmatory tests.[1] They are rapid, simple, and specific and can be used to discriminate between closely related analogs and isomers. The Scientific Working Group for the Analysis of Seized Drugs (SWGDRUG) classifies microcrystal tests as a Category B technique, recognizing they have a greater discriminatory potential than other presumptive tests. Crystals with characteristic shape, habit, and optical activity are formed when the drug is mixed with a precipitating reagent to form specific drug-reagent complexes.[2] Microcrystal tests are not without their limitations. Factors such as concentration, drying time, and adulterants can cause distortion in the crystal shape and habit. The best tests are reliable, quick, and produce recognizable crystals reproducibly with a given drug, like the ones for cocaine and amphetamine. The American Society for Testing and Materials (ASTM) guidelines for cocaine and amphetamine identification have been used by many laboratories to identify these drugs in drug exhibits.

The rise in highly sophisticated instrumental techniques has caused a decline in the use and growth in the area of microcrystal testing; however, because of the advantages described above, it is worth evaluating their performance characteristics with emerging drugs. A quick survey of SWGDRUG monographs reveals that several of the new classes of drugs do not have microcrystal tests described for them. Recently, Elie at al. described the crystals for selected drugs using mercuric chloride as a reagent.[3] The study describes the benzylpiperazine test, mephedrone test, and crystals of potential interferences such as caffeine. The study demonstrates that microcrystal tests can be used to analyze new psychoactive substances with traditional reagents.

This presentation evaluates well-established reagents and their reactions with compounds representing five classes of emerging psychoactive substances: piperazines, phenethylamines, tryptamines, aminoindanes, and cathinones. Each psychoactive substance is thoroughly studied with reagents such as gold and platinum bromides, gold and platinum chlorides, mercuric chloride, and iodide. The presentation discusses the behavior of each analyte with specific reagents under different conditions as well as the selectivity, repeatability, and reproducibility of each test.

Overall, the reagents with gold and platinum showed consistent drug-reagent crystals. Some structurally similar compounds that gave the same crystal shape and habit can be differentiated by the dichroism observed under cross-polars. Different crystal characteristics were observed for the salt and freebase forms of compounds.

This study will help analysts determine if the microcrystal tests can be adopted in their current analytical scheme to complement the instrumental techniques.

B33 Sample Introduction Studies for Direct Analysis in Real-Time (DART®) Systems

Rachel Masek, BS, Eastern Kentucky University, 4112 NSB, 521 Lancaser Avenue, Richmond, KY 40475; Amelia Hartman, Eastern Kentucky University, 4112 NSB, 521 Lancaser Avenue, Richmond, KY 40475; and David Cunningham, PhD, 5142 NSB, 521 Lancaster Avenue, Richmond, KY 40475*

After attending this presentation, attendees will better understand the sample introduction methods currently available for DART® systems and designs with improved performance characteristics. Fundamental aspects of the DART® source ionization and optimization will be reviewed along with steps taken during the optimization of key instrumental parameters. Several examples of applications will be provided, including the analysis of trace drug residues on clothing.

This presentation will impact the forensic science community by providing a sound fundamental description of currently available methods for sample introduction into DART® systems. While DIP-It™ glass tips and QuickStrip™ cards provide rapid analysis options for some types of samples, additional options based on membranes and adhesive tapes will be presented. The potential advantages that these options offer for several types of samples, including drug residue on clothing and skin, will be described.

Sample introduction methods for DART® systems include DIP-It™ glass tips which are dipped into liquid solutions and QuickStrip™ cards which consist of a metal wire mesh that can be placed into powder with some sample adhering to the mesh.[1] Custom sample holders have been made from cotton tip swabs with introduction on a motorized rail system.[2] Results from these devices indicate that analyte signal is generally obtained from the edges of the device where ionized gasses can interact with the sample and the resulting analyte ions are allowed to flow unimpeded into the mass spectrometer. In fact, a cotton swab placed in front of the inlet may result in negligible signal due to blockage of the analyte ions.[2] The present work involves the design of materials with large edge surface areas and geometries conducive to high gas flow rates. Initial material screening studies will be presented that include monitoring of background ions generated by the DART® source ions under various conditions (discharge needle voltage, gas steam temperatures, etc.). Studies were performed using a Simplified Voltage and Pressure (SVP) ion source interfaced to a Linear Trap Quadropole (LTQ) XL™ linear ion trap mass spectrometer with data analysis using the Thermo Xcalibur™ software. Custom holders were constructed and placed inline between the DART® source outlet and the ceramic tube leading to the Vapur™ flange before the inlet to the mass spectrometer. Materials were identified that could readily transfer drug residues from clothing and skin for analysis. The new designs and materials allow facile transfer of trace residues for rapid analysis. The methods represent a substantial improvement to the uncontrolled "wanding" of a sample held by tweezers in front of the mass spectrometer inlet.

DART®, Drug Analysis, Sample Preparation

B34 The Detection of Bleach (Sodium Hypochlorite) in Dialysis Blood Lines and Syringes in a Serial Murder Investigation

S. Frank Platek, MS, US FDA, Forensic Chemistry Center, 6751 Steger Drive, Cincinnati, OH 45237-3097; John B. Crowe, BS, US FDA Forensic Chemistry Center, 6751 Steger Drive, Cincinnati, OH 45237; and David S. Jackson, BS, US FDA Forensic Chemistry Center, 6751 Steger Drive, Cincinnati, OH 45237*

After attending this presentation, attendees will understand what analytical techniques can be used to detect bleach (sodium hypochlorite) in difficult matrices and how this information was used in court to convict a serial murderer for assaulting and murdering several patients at a dialysis facility.

This presentation will impact the forensic science community by shedding light on bleach detection in difficult matrices and the possibility for identifying bleach even when all of its active ingredients have broken down.

After a series of unexplained deaths and adverse reactions of patients at an eastern Texas dialysis center over a one month period, the state initiated an investigation that led to the arrest of a licensed practical nurse who worked at the center. The nurse was accused of murdering five dialysis patients and injuring five additional patients by injecting their dialysis blood lines with bleach (sodium hypochlorite) during their treatments.

The detection of bleach is challenging because sodium hypochlorite rapidly degrades in matrices that can be oxidized. Methodology to characterize bleach and its breakdown products in product tampering investigations has been developed at the Forensic Chemistry Center (FCC). This has been used to determine bleach adulteration in product tamperings even when all of the active hypochlorite has degraded. This is accomplished using a combination of spot tests for oxidizing agents, iodometric titration to assay sodium hypochlorite content, and ion chromatographic analysis for chloride and chlorate (bleach degradation products). In addition, headspace Gas Chromatography/Mass Spectrometry (GC/MS) has been used in some cases to further characterize the interaction of bleach with the sample matrix.

Eight dialysis blood lines and numerous needles and syringes from suspected victims at the dialysis clinic were received at the FCC for analysis. Liquid collected from various sites on the blood lines, residue on discarded syringe needles, and contents of suspect syringes were all analyzed for bleach and bleach degradation products. In addition, Fourier Transform Infrared (FTIR) analysis was used to test crystalline residues from suspect syringes to detect sodium hypochlorite and chlorate. Puncture analyses were performed on selected dialysis line injection ports to determine the number of punctures and to characterize the puncture holes as an indication of tampering. The analysis results were presented in court; the accused was found guilty on five counts of capital murder and three counts of aggravated assault.

Bleach (Sodium Hypochlorite), Serial Murder, Dialysis

B35 Comparison of the Restek Rtx®-5, Rxi®-1ms, and Rxi®-1HT Gas Chromatography (GC) Columns for the Qualitative Analysis of Synthetic Cannabinoids

Laurel A. Hardy, BS, 1412 7th Avenue, Apt #21, Huntington, WV 25701; Carrie J. Kirkpatrick, BS, 725 Jefferson Road, South Charleston, WV 25309; Pamela J. Staton, PhD, Marshall University Forensic Science MSFS & Center, 1401 Forensic Science Drive, Huntington, WV 25701; and Lauren L. Richards-Waugh, PhD, Marshall University, 1401 Forensic Science Drive, Huntington, WV 25701*

After attending this presentation, attendees will better understand the difficulties of synthetic cannabinoid analysis in a high-throughput setting and gain insight as to what GC columns could be put to use in the laboratory to improve the efficiency of synthetic cannabinoid analysis.

This presentation will impact the forensic science community by providing results from a comparison of synthetic cannabinoid qualitative analysis using the Restek Rtx®-5, Rxi®-1ms, and Rxi®-1HT GC columns. This research could impact law enforcement efforts by serving as a resource for all forensic drug laboratories searching for ways to make their analysis of synthetic cannabinoids more efficient.

As popularity of synthetic cannabinoids and the prevalence of their harmful side effects grow, so does the need to control such substances. For high-throughput laboratories such as the West Virginia State Police (WVSP) Drug Identification Laboratory, the high molecular weight and low volatility of synthetic cannabinoids poses a problem for analysis as not all synthetic cannabinoids elute within the parameters of their standard Gas Chromatography/Mass Spectrometry (GC/MS) method. This study compares the Restek Rxi®-1ms and Rxi®-1HT GC columns to the Restek Rtx®-5 GC column (standard in the WVSP Drug Laboratory) to determine if either column could improve the efficiency of synthetic cannabinoid analysis using the standard GC/MS method.

A total of 53 synthetic cannabinoid standards were analyzed and the results indicated a dramatic decrease in retention time (average of 2.106 minutes) when using the Restek Rxi®-1HT GC column for analysis and a slight decrease in retention time (average of 0.488 minutes) when using the Restek Rxi®-1ms GC column for analysis. Data from both the Restek Rxi®-1ms and Rxi®-1HT columns were determined to be statistically significantly different from data obtained using the Restek Rtx®-5 column, based on paired *t*-tests with 95% confidence intervals. Both columns demonstrated adequate reproducibility of retention time for the qualitative analysis purposes of the WVSP Drug Identification Laboratory. In conclusion, the Restek Rxi®-1HT and Rxi®-1ms columns proved to be a promising possibility for the qualitative analysis of synthetic cannabinoids in high-throughput laboratories.

Synthetic Cannabinoid, Gas Chromatography, Qualitative

B36 Colorimetric-Based Paper Microfluidic Devices for the Presumptive Determination of Seized Drugs

Ling Wang, MS, Florida International University, CP-304 11200 SW 8th Street, Miami, FL 33199; Bruce R. McCord, PhD, Florida International University, Dept of Chemistry, University Park, Miami, FL 33199; Giacomo Musile, PhD, Università Di Verona, p.le Scuro 10, Dept Legal Medicine, Verona 37134, ITALY; Jashaun Bottoms, Tuskegee University, 1200 W Montgomery Road, Tuskegee, AL 36088; and Franco Tagliaro, PhD, MD, Dept of Medicine & Public Health, Policlinico GB Rossi, P. le Scuro No. 10, Verona 37134, ITALY*

The goal of this presentation is to describe the development of colorimetric-based paper microfluidic devices for the presumptive determination of seized drugs. Information provided will include the optimized design of a multi-channel paper microfluidic device, the multiplexed detection of different controlled substances, and the development validation of the multi-channel paper chip.

This presentation will impact the forensic science community by demonstrating the application of this newly designed paper microfluidic device in the presumptive detection of seized drugs. The new method is rapid, inexpensive, and applicable to a wide variety of seized drugs.

Colorimetric reagents have been used for testing seized drugs for many years. Although these reagents provide a useful presumptive determination, they are less convenient and more dangerous because of the presence of toxic and corrosive chemicals. This research provides an alternative platform for colorimetric detection based on paper microfluidics. To this end, six-channel chips were created that adapt these colorimetric reagents to a multiplexed ready-to-use format. Each lane performs a different test. In the field, samples are dissolved in a carrier solvent in vials, then applied to the paper just prior to analysis. These devices can be used at crime scenes, laboratories, and any other locations where seized drugs need detection. These paper microfluidic devices are easy to prepare, inexpensive to operate, and can be conveniently stored for later use with shelf lives of two to three months.

The paper microfluidic devices are designed as a six-channel multiplexed system. Preparation of the devices requires a wax-ink printer, thermal laminator, chromatography paper, and colorimetric reagents. The wax-ink printer and a thermal laminator produce hydrophilic channels defined by melted wax on the paper. Next, a variety of different colorimetric reagents are prepared and a different test is prepared for each channel to create six simultaneous and separate detection zones. Drugs in powder form are dissolved in solutions then transferred to the chips where they move to the detection zone via capillary action. Sequences of different reagents can be applied to each channel to produce a series of reactions and the color changes appear at the end of each channel. The entire process takes less than five minutes. Because each specific drug can produce a color change that depends on the specific reagent in each channel, it becomes possible to presumptively determine the type of drug in the test solution.

One important aspect of this study is the selection of potential reagents for the device. Traditional colorimetric reagents, such as the Mandelin and Froehde reagents, use concentrated sulfuric acids. Acids such as sulfuric acid and nitric acid can burn and digest chromatographic paper. As a result, a variety of chemical tests were performed to modify these reagents in order to make them more compatible with the paper-based format. For example, potassium manganate (VII), copper (II) sulfate, and iron (III) have been utilized in various forms to create alternate colorimetric reagents. The adjusted reagents produce specific color changes for seized drugs on the paper microfluidic devices. Procedures have been developed for the detection of cocaine, ketamine, codeine, ephedrine, morphine, amphetamine, methamphetamine, and MDMA. These devices have been tested for sensitivity, specificity, and stability against a variety of potential interferences and test conditions.

The use of paper microfluidic devices permits the development of rapid, inexpensive, and easily operated tests for a variety of seized drugs. They present a safe and convenient presumptive tool for samples that can be used in the field, prior to confirmatory laboratory analysis.

Paper Microfluidic Devices, Colorimetric Reagents, Seized Drugs

B37 Evaluation of Microscopy and Vibrational Spectroscopy for the Discrimination of Purple and Blue Nail Polishes

Brianna Kroon, 4333 Wells Curtice Road, Canandaigua, NY 14424; Elaine M. Pagliaro, JD, University of New Haven, Lee Institute of Forensic Science, 300 Boston Post Road, West Haven, CT 06516; and Brooke W. Kammrath, PhD, University of New Haven, Forensic Science Dept, 300 Boston Post Road, West Haven, CT 06516*

After attending this presentation, attendees will understand the discriminating power of microscopic and spectroscopic analytical methods for the analysis of blue and purple nail polishes.

This presentation will impact the forensic science community by evaluating the discriminating potential of microscopic and spectroscopic methods for the analysis of blue and purple nail polishes.

Nail polish is a common and popular quick-drying lacquer that is painted on fingernails or toenails for aesthetic purposes. Nail polish falls under the category of cosmetic evidence and limited research has been performed regarding the evaluation of microscopy (stereomicroscopy, brightfield, and polarized light) and spectroscopy (infrared and Raman) as these techniques relate to nail polish as cosmetic evidence. Although identification and discrimination of nail polish is not commonly practiced by forensic scientists, cosmetic evidence and, more specifically, nail polish has played a key role in criminal cases. Most infamously, nail polish was valuable forensic evidence in the "Wood Chipper Murder Case" in Connecticut. Nail polish is either a transparent or colored lacquer that contains the following basic components: film forming agent, resins or plasticizers, solvents, and coloring agents. Each component has a different purpose: the film-forming agent creates a protective layer over the polish; the plasticizer or resin improves flexibility of the nail polish and makes the nail polish more resistant to water and soap; the volatile solvents hold the mixture of materials and colorings until the polish is applied; and the coloring agent, which is comprised of organic dyes or inorganic pigments, contributes to the overall color of the nail polish.

Nail care is a large part of the cosmetic industry, with global sales in 2014 estimated to be nearly $1.2 billion. Nail art not only follows trends but is also viewed as a form of personal expression, which is why there is a plethora of available colors. This study focused on blue and purple nail polishes, which have not yet been studied by the forensic science community.

The discrimination power of microscopic and spectroscopic methods was evaluated in this research. Seven different brands of nail polish with seven different shades of purple and blue per brand of nail polish were analyzed. The shade of blue and purple were chosen to be as similar as possible between the brands, and a variety of brands were chosen to represent a selection of salon-quality polishes as well as polishes intended for at-home use. A total of 49 different polishes were analyzed using three types of microscopy (stereomicroscopy, brightfield, and polarized light microscopy) and two types of spectroscopy (Raman and attenuated total reflection Fourier Transform infrared microspectroscopy) in order to determine whether these methods could provide discrimination between the 49 bottles of blue and purple nail polish and/or brand identification.

All 49 bottles of nail polish were able to be discriminated microscopically, based on various pigment characteristics (i.e., size, dispersion, density, color, etc.), as were the presence of distinct effect pigments in some of the samples. Raman spectroscopy was successful in identifying some pigments in the polishes, specifically Pigment White 6 (anatase) and Pigment Blue 27; however, there was fluorescence in several samples that prevented pigmentation identification for every blue and purple polish. Infrared spectroscopy was used for brand identification, with Principal Component Analysis/Canonical Variate Analysis (PCA/CVA) hold-one-out cross validation proving to have a 1.9% error rate. The results from this research provide valuable information about cosmetic evidence that criminalists can use in investigations and adjudications.

Nail Polish, Microscopy, Spectroscopy

B38 Characterization by Scanning Electron Microscopy With Energy-Dispersive X-Ray Spectroscopy (SEM/EDX) of Nail and Gel Polishes and Its Real-World Applications

Audriana M. Wagner, University of New Haven, 300 Boston Post Road, West Haven, CT 06516; R. Christopher O'Brien, PhD, University of New Haven, Dept of Forensic Science, 300 Boston Post Road, West Haven, CT 06516; Elaine M. Pagliaro, JD, University of New Haven, Lee Institute of Forensic Science, 300 Boston Post Road, West Haven, CT 06516; and Brooke W. Kammrath, PhD, University of New Haven, Forensic Science Dept, 300 Boston Post Road, West Haven, CT 06516*

After attending this presentation, attendees will better understand the characterization and discrimination power of SEM/EDX for the forensic analysis of nail and gel polishes. In addition, real-world samples degraded in air, static freshwater, and dynamic freshwater environments were analyzed to assess changes in their elemental composition.

This presentation will impact the forensic science community by determining the characterizing and discriminating potential of SEM/EDX for the forensic analysis of nail and gel polishes as well as evaluating the effects of degradation on those results.

Because of their wide availability, popularity, and durability, nail polishes are an important type of cosmetic evidence. Although cosmetic evidence is not widely analyzed by forensic scientists, these types of evidence have proved to be incredibly valuable in a plethora of cases including the infamous "Wood Chipper Murder Case" in Connecticut. Traces of nail polish can be left at a location or transferred between individuals in a variety of ways, and the ability to associate a sample with the source (bottle and/or brand) is of the utmost importance.

SEM/EDX instrumentation is not only valuable for viewing powerful high-resolution microscopic images of samples but also for measuring their elemental composition. This instrumentation is commonly used to analyze trace paint evidence gathered from the scenes of hit-and-runs or burglaries for identification purposes. Nail and gel polish composition is complex and actually very similar to that of paint, which is the impetus for evaluating SEM/EDX performance in terms of nail and gel polish characterization and identification.

In this study, the effectiveness of SEM/EDX instrumentation was explored for the characterization of visually similar nail and gel polishes in red and pink hues. Seven different brands were chosen for each type of polish for a total of 14 brands. From each brand, seven colors of similar shades were selected as samples resulting in a total of 124 analyzed polishes including top and base coats from each brand. The brands used were a mix of salon quality polishes and polishes intended for at-home use. Additionally, painted nail clippings underwent extensive degradation studies in air, static freshwater, and dynamic freshwater environments, which were similarly analyzed by SEM/EDX to measure the degradation effects from each environment over a time period of one month. These degradation studies of painted human fingernails mimicked submissions of evidence to a forensic laboratory and offer real-world information on the decay of nail and gel polishes in the tested environments.

This study evaluated the forensic relevance of SEM/EDX instrumentation for the analysis of nail and gel polishes by comparing elemental compositions of the selected polishes. Multivariate statistical analysis methods, such as Principal Component Analysis/Canonical Variate Analysis (PCA/CVA), pair-wise comparisons, and standard deviation match criteria were used to assess the discrimination ability of the instrumental methods used for both characterization and degraded samples. Results indicate that although brands and bottles could not be uniquely identified because of similar elemental profiles, this technique would be useful for exclusion. This research provides valuable information to the field of forensic science, specifically for the analysis of cosmetic evidence, where a gap in the literature exists.

Cosmetic Evidence, Forensic Science, SEM/EDX

B39 The Analysis and Classification of Tire Rubber Deposits Using Pyrolysis-Gas Chromatography/ Mass Spectrometry (Py-GC/MS)

Rebecca Thielen, BS, 427 N Milton Avenue, Campbell, CA 95008*

After attending this presentation, attendees will better understand a successful recovery method for tire rubber deposits left as a result of skidding or braking incidents at the scene of a crime, the role that road surface plays as a contaminant, and the ability to associate these rubber deposits with the tire from which they originated.

This presentation will impact the forensic science community by contributing valuable and novel information on a topic with little previous research, none of which was previously conducted in the United States. This presentation will encourage forensic scientists to recognize this as a useful type of evidence within the forensic trace field as well as demonstrate an effective method for tire analysis that can be performed in crime laboratories.

Many crimes involve the use of motor vehicles and, as a result, impressions or tire deposits may be left behind. This type of evidence has the ability to provide forensic scientists with information about a vehicle's tires, such as tread pattern and brand, and therefore possibly information about the vehicle size or type.[1] Oftentimes, these impressions and markings are not of the best quality and provide very little probative information. In these cases, it would be beneficial to be able to analyze tire rubber deposits left at a scene; however, comprehensive studies have not been done on this topic. Previous research has identified Py-GC/MS as a successful method in the analysis of rubber deposits. These studies have shown this instrument's ability to distinguish between different manufacturers of tires as well as between different tire models of the same manufacturer on the basis of tire tread chemical composition.[2,3] Other studies have confirmed these findings, as well as applied statistics to help determine that there is low intra-variability within each tire and a high enough inter-variability between tires to correctly assign deposits to their source tire.[4] While this research has explored some sample collection methods and has acknowledged the possibility of road surface contamination, neither have been comprehensively studied.

In this experiment, tire deposits were made on both concrete and asphalt by eight different vehicles, each with a different brand or model of tire. Immediately following each deposit, both concrete and asphalt surfaces were tape lifted separately to collect any rubber deposits left behind. A thin slice of tread was removed from four different areas of each tire that made a deposit. Using a stereomicroscope, each tape lift was examined and rubber deposits were removed with tweezers. Each was analyzed separately using a validated rubber method adapted from previous research on the Py-GC/MS.[4,5] Four tire tread samples from the tire that made the corresponding tire deposit were then run on the Py-GC/MS. Control samples of the asphalt and concrete were collected and analyzed to account for any contamination. The resulting chromatograms were superimposed and compared to study retention times and overall peak patterns. Then, Target Compound Identification (TCI), normalization, and peak area were used to determine whether different tires had distinguishing chromatograms and if tire deposits had the same chromatograms as their corresponding tire tread samples.

Extracted ions and TCI were used to classify each sample based on its primary rubber content. Six of the eight samples were classified as Styrene-Butadiene Rubber (SBR) and the other two as a mix of SBR and Natural Rubber (NR). The data was normalized to the styrene peak for SBR samples and the limonene peak for SBR/NR samples. In addition to normalization, the peak area, relative intensity, and extracted ions were used to help further classify each group based on the presence of small amounts of additives that differ between tire models and brands. Concrete and asphalt surfaces do contribute a small amount of contamination, but it does not interfere in the association of the deposit to the tire from which it originated. This preliminary analysis of the data reveals two important conclusions: (1) there are noticeable differences in chemical composition between different brands and models of tires; and, (2) tire deposits have the same composition as the tire tread samples from which they originated. The use of tape lifts as a recovery method in this study proved to be successful compared to other methods tested. The tape lifts collected a sufficient amount of tire residue for analysis without any significant interference from the adhesive. This method worked even in situations in which cars left very light deposits behind.

In conclusion, this study demonstrates that not only can different types and models of tires be differentiated from one another, but their rubber deposits can also be differentiated from one another as well as associated to the tire from which they originated. The findings from this research could be used to develop specific tire deposit recovery methods to be used during evidence collection as well as integrate tire rubber analysis as an examination that crime laboratories perform.

Rubber Deposits, Tires, Pyrolysis

B40 Organization of Scientific Area Committees (OSAC) Activities Impacting Laboratory Operations

John P. Jones II, MBA, National Institute of Standards & Technology, 100 Bureau Drive, MS 8102, Gaithersburg, MD 20899*

After attending this presentation, attendees will understand the latest standards and guidelines reviewed by the OSAC for Forensic Science and their potential to impact laboratory operations. The OSAC is comprised of 33 operating units and more than 100 task groups populated by 540 OSAC members and 150 affiliates, all working on specific standards activities.

This presentation will impact the forensic science community by educating attendees on the standards and guidelines reviewed by the OSAC and how implementation of these standards in the forensic science community is likely to occur. Instructions will also be provided on how individuals can become involved with the OSAC and can have an impact on standards development efforts.

The OSAC has been fully operational since January 2015 and continues to transition the fragmented standards development efforts in the forensic industry to a unified process of recognizing valuable standards and guidelines that have both scientific merit and wide-based community acceptance. OSAC subcommittees have reviewed an initial National Institute of Standards and Technology (NIST) -developed catalog of external standards and guidelines that contained more than 700 documents that existed prior to OSAC. As part of the OSAC development and review process, subcommittees determine if documents have scientific merit and if they were developed through an open standards development process. In addition, documents are reviewed to determine if they have addressed legal and human factors issues and have properly documented the potential impact on existing laboratory operations. From this effort, the 24 OSAC subcommittees have selected specific documents to route for approval to post on OSAC registries or, in many cases, to further develop with the intention of enhancing a document's scientific basis and/or range of public input received.

With forensic science practitioners, researchers, statisticians, and measurement scientists collaborating to bolster existing standards and guidelines or develop new standards from scratch, the forensic science community can have confidence in the documents that are approved to be listed on the *OSAC Registry of Approved Standards* and the *OSAC Registry of Approved Guidelines*.

Standards, OSAC, NIST

B41 Organization of Scientific Area Committees (OSAC) — Increasing Visibility of Standards in Forensic Science and the Potential Impact in the Laboratory and the Courtroom

Mark D. Stolorow, MS, MBA, NIST Special Programs Office, Organization of Scientific Area Committees, 100 Bureau Drive, MS 8102, Gaithersburg, MD 20899-8102*

After attending this presentation, attendees will understand how the efforts of more than 700 subject matter experts (volunteers) appointed to the OSAC for forensic science and others could impact laboratory protocols, accreditation efforts, reports, expert testimony, and criminal justice proceedings.

This presentation will impact the forensic science community by illustrating how, as judges, prosecutors, and defense attorneys become acquainted with the *OSAC Registry of Approved Standards* and *OSAC Registry of Approved Guidelines*, direct and cross examination of expert witnesses will increasingly examine conformance with the published standards and guidelines used in conducting the forensic analysis and interpreting data. Expert witnesses will increasingly need to confirm in testimony the scientific validity of their protocols and candidly share with juries any limitations of their analyses and interpretations.

The OSAC design employs the essential requirements of developing consensus-based standards, which include openness, transparency, balance of interest, due process, and an appeals process that ensures each stakeholder's viewpoints are properly considered. In addition, the OSAC infrastructure brings a uniform standards recognition platform to the community, enhances scientific rigor, and increases communication among forensic scientists, research scientists, academicians, statisticians, attorneys, managers, and quality-assurance specialists. The OSAC structure consists of a Forensic Science Standards Board, three resource committees, five scientific area committees, and 24 subcommittees.

This presentation will impact the forensic science community by educating attendees on the processes employed by the OSAC to identify, foster development, and formally approve forensic science standards through publication on the *OSAC Registry of Approved Standards* and *OSAC Registry of Approved Guidelines*. These standards and guidelines will be implemented voluntarily by practitioners and incorporated into auditing processes by accreditation bodies. The high visibility of approved standards and guidelines on the OSAC registries will ultimately impact quality standards for report writing and expert testimony in the courtroom.

As the forensic science community is aware, the development of a quality infrastructure for forensic science was a key component of some of the reforms anticipated in the 2009 National Academy of Sciences (NAS) Report, Strengthening Forensic Science in the United States – A Path Forward. OSAC is now operational and beginning to populate the OSAC registries with approved standards and guidelines. As judges, prosecutors, and defense attorneys become acquainted with the *OSAC Registry of Approved Standards* and *OSAC Registry of Approved Guidelines*, direct and cross examination of expert witnesses will increasingly examine conformance with the published standards and guidelines used in conducting the forensic analysis and interpreting data. Expert witnesses will increasingly need to confirm in testimony the scientific validity of their protocols and candidly share with juries any limitations of their analyses and interpretations.

The consensus-based documentary standards and guidelines approved for posting on the OSAC registries will be considered by laboratory directors and quality-assurance managers as standard methods for specific analyses. Accreditation bodies will consider the published discipline-specific standards for incorporation into their International Organization for Standardization (ISO) 17025 supplemental standards. As forensic science practitioners increase employment of quantification, uncertainty measurements, and probabilistic models in casework, there will also be increased utilization of quantitative results and probabilistic data in laboratory reports and expert testimony.

Standards and Guidelines, OSAC, Accreditation

B42 Chemometric Analysis of Gasoline Samples Utilizing Direct Analysis in Real-Time Mass Spectrometry (DART®-MS)

Ashley Davis, MS, Boston University School of Medicine, 72 E Concord Street, Boston, MA 02118; Matthew Pavlovich, PhD, Northeastern University, 360 Huntington Avenue, 140 The Fenway, Boston, MA 02115; Joseph H. LaPointe, BSc, IonSense, Inc., 999 Broadway, Ste 404, Saugus, MA 01906; Brian Musselman, PhD, IonSense, Inc., 999 Broadway, Ste 404, Saugus, MA 10906; and Adam B. Hall, PhD, Northeastern University, 360 Huntington Avenue, 140 The Fenway, 421TF, Boston, MA 02115*

After attending this presentation, attendees will better understand current and past efforts to provide brand differentiation of gasoline, a common ignitable liquid utilized by arsonists worldwide. In this research, DART®-MS was employed as an analytical approach for the analysis of gasoline in an effort to generate chemical attribute signatures for a wide variety of gasoline brands at various states of weathering.

This presentation will impact the forensic science community by providing information pertaining to current research applicable to the fire debris analysis community. This data shows that even in highly evaporated samples (75% and >90%), unique ions can be used to differentiate common gasoline brands from one another in a fraction of the total analysis time in comparison to current analytical approaches.

Gasoline is an easily obtainable ignitable liquid that arsonists commonly use to initiate or expedite the spread of an intentionally set fire. Current methods for the extraction and concentration of ignitable liquids from fire debris utilize passive headspace concentration with activated carbon strips. Typical extractions are conducted between 60°C-80°C for 12-16 hours based on American Society for Testing and Materials (ASTM) guidelines followed by Gas Chromatography/Mass Spectrometry (GC/MS) analysis. Normally, hundreds of low molecular weight hydrocarbons are detected resulting in chromatograms showing distinctive patterns characteristic of various ignitable liquid classes. While traditional GC/MS methods are sensitive and generate data, which can be classified as gasoline based on the ASTM classification scheme, they do not allow for differentiation of brands of gasoline (especially weathered samples) or detect higher mass ions that may permit the determination of unique chemical attribute signatures. Gasoline samples were obtained from various vendors including Shell®, Sunoco®, Irving®, Gulf®, and Cumberland Farms®. An evaporation series was created for each of the brands and analyzed utilizing QuickStrip™ cards by DART®-MS and also by GC/MS methods. The goals and objectives of this research were to optimize the DART®-MS parameters for gasoline analysis, evaluate the potential for DART®-MS to distinguish gasolines by brand, develop chemometric models to appropriately classify gasoline samples, and finally lay the groundwork for future studies that could further develop a more efficient and discriminating DART®-MS gasoline analysis method for forensic casework.

Preliminary studies using DART®-MS to analyze weathered gasoline samples using desorption ionization produced characteristic spectra for various brands of gasoline. Significantly, unique ions were detected in the higher mass range of the spectrum (>m/z 500). Using an ion trap mass analyzer and a scan range of 50amu-1,000amu, mass spectra rich in various ions were detected. Many of these ions are likely gasoline additives and are non-hydrocarbon in their nature. The data shows that DART®-MS detected higher mass ions not observed in the GC/MS data and also showed differential spectra for the varying gasoline brands. Principle Component Analysis (PCA) plots of the data created through these methods have shown that gasoline brands tend to cluster separately from one another, despite the extent of weathering as represented by the evaporation percentage. Using these unique ions and advanced chemometric analysis, statistical analysis software was used to build models that can discriminate analyzed samples in a fraction of the time in comparison to a traditional GC/MS approach. Although variables including the season of purchase, storage time, dilution, and age of the gasoline were observed to contribute to the resulting mass spectral data, once the mass spectra are further evaluated, they could offer even more discriminating power between samples in addition to brand identification. Techniques such as DART®-MS in combination with chemometric approaches could enable forensic laboratories to confidently identify questioned gasoline samples by brand in the future.

Fire Debris, Chemometrics, (DART®-MS)

B43 Using Atmospheric Pressure Chemical Ionization/Mass Spectrometry (APCI/MS) and Flow Injection for the Screening of Arson Accelerants

Clare M. Fried, BS, Cedar Crest College, 100 College Drive, Allentown, PA 18104; Thomas H. Pritchett, MS, 100 College Drive, Allentown, PA 18104; and Michelle Shortell, MS, Pennsylvania State Police, Bethlehem Regional Laboratory, 2932 Airport Road, Bethlehem, PA 18017*

After attending this presentation, attendees will understand a new approach to fire debris analysis and how carbon disulfide, in combination with an APCI source, contributes to a more efficient screening process.[1]

This presentation will impact the forensic science community by providing a new perspective on accelerant detection methods. Some advantages to this method include: (1) the MS-only and precursor scans for the same compound classes as in the American Society for Testing and Materials (ASTM) methods only take minutes to perform; (2) carbon disulfide, the solvent of choice for extraction with carbon strips and passive headspace analysis, has shown the ability as an efficient charge transfer agent in APCI with hydrocarbons; and, (3) using Tandem Mass Spectrometry (MS/MS) analysis provides prominent molecular ion peaks in Q1 scans, as well as provides precursor scans, that identify the same compound classes as the standard Gas Chromatography/ Mass Spectrometry (GC/MS) -extracted ion chromatograms.[2,3]

Every year in the United States, millions of dollars and thousands of businesses and private properties are lost due to intentionally set fires. The forensic fire debris field is a continuously shifting one, which presents constant challenges to those who are involved with the investigations. Arson investigations depend largely on quick detection and determination of ignitable liquids and their residues. Arson fires affect many people across the United States each year and the people responsible for deliberately setting the fires should be caught and held responsible for their crimes.[4,5]

In this study, an APCI-MS/MS method has been developed which has been used to screen common ignitable liquids. A passive headspace sampling technique, along with activated charcoal strips, were used to collect samples. A carbon disulfide reagent was added to each strip once the headspace was collected. The carbon disulfide extract was injected into the MS/MS using a flow injection technique. The MS/MS, an ABI® SCIEX™ 3200 Qtrap® triple quadrupole mass spectrometer, utilized an APCI source and positive-ion mode. A peak-hopping scan mode was employed, along with a step size of 1amu. A Q1 scan and precursor scans were run for each accelerant sample.

Ignitable liquids such as gasoline, diesel, lighter fluid, mineral spirits, turpentine, paint thinner, WD-40®, and kerosene were sampled. Prominent molecular ion peaks provided indications that each accelerant presented a different profile. Five different commercial gasolines were studied as well as four different commercial diesels. The gasoline samples presented similar profiles to each other. The diesel samples presented similar profiles as well. Precursor scans at 91amu and 128amu provided an insight into what contributed to prominent peaks seen in each accelerant sample. Sample profiles were completed using mass range binning and peak intensity sums to create bar graphs for each.[6]

In conclusion, this method could potentially be used in forensic fire debris analysis to screen for accelerants. This method could shorten analysis time considerably. According to the ASTM Standard, GC/MS methods include a total run time of 25.0 minutes.[7] This method cuts down run time to less than three minutes, with no cool-down time.

Fire Debris, Accelerants, APCI

B44 Practical Methods for Prohibiting Microbial Degradation of Ignitable Liquids in Soil Samples

James Hoult, BS, 2100 Paramont Way, Modesto, CA 95355; and Katherine D. Hutches, PhD, ATF, 355 N Wiget Lane, Walnut Creek, CA 94598*

After attending this presentation, attendees will: (1) understand how ignitable liquids found in soil are degraded; (2) understand why this type of evidence should be refrigerated to prevent degradation; and, (3) be aware of new possible, practical alternatives to refrigeration.

This presentation will impact the forensic science community by offering arson investigators and analysts a new practical alternative to refrigeration to prevent microbial degradation of ignitable liquids. Prohibiting the degradation of ignitable liquids before they can be analyzed in the laboratory will increase the odds that ignitable liquids in problematic samples will be identified using Gas Chromatography/Mass Spectrometry (GC/MS), even when refrigeration is not possible.

It has been well established that microbes in soil and moldy building materials can degrade ignitable liquids through preferential degradation of select compounds.[1,2] Refrigerating soil samples with potential ignitable liquid samples has been found to slow microbial degradation, but this requires large amounts of refrigerated space that are expensive and not always available.[3] Ignitable liquid samples found in soil can also become degraded prior to reaching a laboratory due to the fast rate of degradation. The use of triclosan in place of refrigeration is an exciting development, but pure triclosan is not readily available to fire investigators, would need mixing in the field, and could have possible negative health effects.[3]

Carbon dioxide canisters, dry ice, and oxygen-absorbing pouches were chosen as possible practical alternatives to triclosan. These experiments sought to make the atmosphere in the sampling cans more anaerobic by reducing the amount of oxygen present or replacing the air with carbon dioxide. This is ideal because anaerobic metabolism of ignitable liquids has been shown to be less efficient than aerobic metabolism.[4]

To test if carbon dioxide canisters could prohibit microbial degradation, an adjustable bicycle tire inflator was used to displace the air in the cans with carbon dioxide. Positive samples were spiked with 20µL of gasoline or diesel. The cans treated with carbon dioxide were compared to spiked soil samples that were kept at room temperature or in a freezer. In early experiments, the addition of carbon dioxide appeared to prohibit microbial degradation; however, with further testing it was shown that carbon dioxide canisters are unreliable as a means of prohibiting microbial degradation. It was also evident that there was wide variation in the canisters' contents.

Dry ice was also tested as a possible alternative to the carbon dioxide canisters. Dry ice offered less potential contamination than carbon dioxide canisters and cooling of the soil to help prohibit degradation; however, the sublimation of the solid dry ice to gas caused the pressure in the cans to increase and several lids exploded off the cans. The small amounts of dry ice that could safely be used failed to stop microbial degradation.

Finally, Oxy-Sorb® pouches were added to cans of soil spiked with gasoline. Oxy-Sorb® pouches are used to keep food fresh by reducing the amount of oxygen that is present.[5] The pouches are iron-based oxygen scavengers that reduce the available oxygen due to the reaction of oxygen with ferrous iron.[5] The samples with Oxy-Sorb® pouches added were compared to gasoline-spiked soil samples that were kept at room temperature. The Oxy-Sorb® pouches prohibited microbial degradation for 28 days.

Oxy-Sorb® pouches are a promising alternative to refrigeration and could be used in the future to prohibit microbial degradation. Before the Oxy-Sorb® pouches can be reliably used to stop microbial degradation, further experiments are needed using ignitable liquids other than gasoline. Other brands and sizes of oxygen-scavenging pouches could also be explored.

Fire Debris, Microbial Degradation, Ignitable Liquid

B45 The Surprising Effect of Temperature on the Weathering of Gasoline

Heather Birks, BS, Virginia Commonwealth University, 1015 Floyd Avenue, Rm 2015, Richmond, VA 23284; Ashley Cochran, BS*, West Virginia University, Oglebay Hall, Morgantown, WV 26505; Tyler Williams, 98 Hearthstone Way, Hanover, MA 02339; and Glen P. Jackson, PhD, West Virginia University, Dept of Forensic and Investigative Science, 208 Oglebay Hall, Morgantown, WV 26506-6121*

After attending this presentation, attendees will understand how the evaporation temperature affects the distribution of remaining compounds after gasoline samples have been weathered to simulate fire debris samples.

This presentation will impact the forensic science community by providing practitioners with an explanation of why gasoline samples often do not appear to be evaporated to the same extent as one might expect based on the very high temperatures of structure fires.

Arson investigations often involve the identification and characterization of ignitable liquid residues in fire debris. The most commonly used ignitable liquid is gasoline because it is so readily available and particularly effective. Gasoline often evaporates from its containers during storage as well as through exposure to high temperatures, such as during a fire. Such evaporation is often termed weathering, and it is widely accepted that ignitable liquid residues are more likely to resemble weathered liquid samples than pristine liquid samples.

Prior research has investigated the weathering characteristics of gasoline under a variety of experimental conditions, but to date this has been limited to basic pattern recognition of the resulting chromatograms. Relatively little work has been performed to understand how weathering conditions — such as temperature, pressure, or convection — affect the distribution of the various classes of volatile components. For the current study, gasoline samples were weathered at atmospheric pressure using a stream of nitrogen gas and under vacuum. At both pressures, samples were weathered to 75%, 90%, and 95% by weight and at three different temperatures of 25°C, 60°C, and 90°C. After weathering, samples were analyzed using an Agilent® Gas Chromatograph/Mass Spectrometer (GC/MS) with conventional conditions on a 30m DB5 column. The resulting chromatograms showed that the earliest eluting, most volatile compounds — like toluene and the C_2-alkyl benzenes — tend to remain at significantly ($\alpha<0.05$) higher levels at higher temperatures relative to weathering to the same level at lower temperatures.

For example, at 75% weathering, samples weathered at 90°C had toluene and C_2-alkyl benzene peaks that were three to four times more abundant than samples weathered at room temperature ($\alpha\sim1x10^{-7}$, $n=20$). At 90% and 95% weathering, the same peaks were typically below threshold when weathered at 25°C and 60°C, but were typically above threshold when weathered at 90°C. The use of nitrogen had a small effect on weathering, but was insignificant relative to the temperature effect. The consequence is that samples weathered at higher temperatures appear less weathered (on a percent level) than one would expect. These results are consistent with the known relationships between vapor pressure and temperature for the different compounds. The relationship between vapor pressure and temperature was further validated by weathering of a simplified synthetic mixture of seven compounds found in gasoline, and the simulated (purely theoretical) weathering of the same compounds based on published Antoine constants.

This study may help explain why real fires often cause gasoline residues to appear far less weathered than one would expect based only on the expected weathering temperatures.

Arson, Gasoline, Weathering

B46 Mathematically Modeling Chromatograms of Evaporated Ignitable Liquids for Fire Debris Applications

Rebecca J. Brehe, BS, 6180 Bluff Road, Washington, MO 63090; John W. McIlroy, PhD, Drug Enforcement Administration, 10150 Technology Boulevard, E, Dallas, TX 75220; Ruth Waddell Smith, PhD, Michigan State University, School of Criminal Justice, 560 Baker Hall, East Lansing, MI 48824; and Victoria L. McGuffin, PhD, Michigan State University, Dept of Chemistry, East Lansing, MI 48824-1322*

After attending this presentation, attendees will be familiar with a mathematical model that can be used to generate chromatograms of ignitable liquids evaporated to different levels. The mathematically generated chromatograms can be used to populate reference databases that are used to aid in the identification of ignitable liquids in fire debris samples.

This presentation will impact the forensic science community by providing a method to generate the chromatogram of an ignitable liquid at any level of evaporation, thereby overcoming the variable and time-consuming nature of evaporating ignitable liquids experimentally.

Fire debris samples are typically extracted and analyzed by Gas Chromatography/Mass Spectrometry (GC/MS) to identify any ignitable liquid present. Identification is based on comparison of chromatograms to a database of ignitable liquid reference standards with mass spectral interpretation to identify specific compounds. To account for chemical changes in the liquid that occur during the fire, reference standards experimentally evaporated to different levels are often included in these databases; however, there are numerous variables to consider in performing an evaporation, all of which affect the rate of evaporation. Further, evaporating liquids experimentally can be time consuming, particularly for less volatile liquids (e.g., heavy petroleum distillates) and, as a result, the database may be limited in the number of liquids or levels of evaporation that are included.

In this research, a previously developed mathematical model was further investigated for applications in fire debris analysis. Briefly, the model, which is based on first-order kinetics, is used to predict evaporation rate constants for each compound in the ignitable liquid as a function of retention index. For a given evaporation level, the rate constants are used to predict the fraction of each compound remaining. The fraction remaining is plotted versus retention index to generate a fraction remaining curve for a given evaporation level. This curve is multiplied by the chromatogram of the unevaporated liquid to generate the chromatogram corresponding to that evaporation level.

To test the application of the mathematical model, three petroleum distillates (spanning the light to heavy subclasses) and gasoline were analyzed in the unevaporated state by GC/MS using a 100% dimethylpolysiloxane stationary phase, which was necessary to allow calculation of retention indices. The model was applied to the chromatogram of each unevaporated liquid to generate chromatograms corresponding to evaporation levels of 25%, 50%, 75%, and 90% by mass. Each liquid was also evaporated experimentally to the same levels and analyzed by GC/MS in a similar manner. The chromatograms of the evaporated liquids generated using the model and those derived experimentally were compared using Pearson Product-Moment Correlation (PPMC) coefficients. These coefficients offer a pairwise comparison to assess similarity between the chromatograms, with coefficients greater than 0.8 indicating strong correlation.

For the petroleum distillates, PPMC coefficients indicated strong correlation between the mathematically generated chromatogram and the corresponding experimentally derived chromatogram; however, there was a slight decrease in PPMC coefficient as evaporation level increased. For example, PPMC coefficients between the experimental and mathematically generated kerosene chromatograms ranged from 0.9942±0.0005 at 26% evaporated by volume to 0.954±0.002 at 90% evaporated by volume.

For gasoline at the 25% evaporation level, PPMC coefficients indicated a strong correlation between the mathematically generated and experimentally derived chromatograms (0.9620±0.0014). The PPMC coefficients again decreased as evaporation level increased; however, in this case, the strength of the correlation also decreased, with a PPMC coefficient of 0.535±0.015 at the 90% evaporation level, which indicates only moderate correlation. The lower correlation occurred in part due to the mass of highly volatile compounds present in gasoline. These compounds eluted before and during the solvent front, meaning that they were not detected using the current GC/MS method. After taking these compounds into account, the correlation between the mathematically generated and experimentally derived chromatograms increased to 0.986±0.002 at the 90% evaporation level, indicating strong correlation. This presentation will describe the application of the model and indicate ways in which this model could be applied in fire debris analysis.

Mathematical Modeling, Evaporation, Fire Debris Analysis

B47 Characterization of Aluminum (Al) Powders in Explosives Utilizing Particle Micromorphometry

JenaMarie Baldaino, BS, 5012 Coachmans Carriage Terrace, Glen Allen, VA 23059; Danica Ommen, MS, South Dakota State University, Mathematics & Statistics, Box 2220, Brookings, SD 57007; Joshua Dettman, PhD, 2501 Investigation Parkway, Quantico, VA 22135; Raleigh Parrott II, 2501 Investigation Parkway, Quantico, VA 22135; Jack Hietpas, PhD, FBI-ORISE, 2501 Investigation Parkway, Quantico, VA 22135; and JoAnn Buscaglia, PhD, FBI Laboratory, CFSRU, 2501 Investigation Parkway, Quantico, VA 22135*

After attending this presentation, attendees will better understand the forensic potential of automated particle micromorphometry to aid in making comparisons between questioned and known Al powders. In addition, the results from this study may help provide insight into the method of Al powder manufacturing.

This presentation will impact the forensic science community by demonstrating the application of aluminum particle micromorphometry as a quantitative method for the characterization and comparison of explosive evidence, which may also provide valuable lead identification for forensic investigations.

Al powders have a wide variety of legitimate uses, are widely available without significant regulatory constraints, and are commonly used in pyrotechnics and explosives as a fuel to increase the heat of explosion.[1,2] Al powders can be bought from manufacturers or can be made inexpensively at home using basic instructional manuals and videos.[3] Due to their ease of production, bomb-makers commonly mix Al powder with ammonium nitrate or RDX to gain larger detonations for the construction of Improvised Explosive Devices (IEDs).[3,4] Al particle size and shape influence how reactive the Al powder will be; smaller particle size and flatter particle shapes will lead to a higher reactivity.[1] This research investigates the potential of using particle micromorphometry to differentiate Al powders, with the goal of comparing Al samples (e.g., known versus unknown source samples) as well as provide insights into production methods.

This presentation builds on the results from a small pilot study that determined that differences in manufacturing methods of Al powder produced differences in particle micromorphometry. A significantly larger-scale study (greater number and variety of samples with more detailed sample pedigrees) is currently being performed. Al powder samples were obtained from legitimate industrial manufacturers, seized IEDs, and "in-house" production from Al flake-containing commercial spray paint and ground Al foil. To replicate amateur methods of Al powder production, Al foil was ground in a consumer-grade blender as well as in a small 6lb rotary dual-drum ball mill. To obtain uniform particle size for high-quality microscopical imaging, the Al powder samples were wet-sieved with disposable polyester mesh. Transmitted light microscope images (*n*1,600 images/sample) of the Al samples were acquired using an automated stage. Dimensional analysis was calibrated using a National Institute of Standards and Technology (NIST) -traceable stage micrometer; polystyrene spheres of 100µm, 50µm, and 10µm were used as secondary standards to assess linear calibration. Images were batch processed using commercial image analysis software and customized code. Each image was pre-filtered using a high-pass filter to enhance edge detection and converted to a binary image. Seventeen parameters were measured for each particle within the image field of view including: area, aspect ratio, perimeter, roundness, mean diameter, mean feret, radii (maximum and minimum distance from particle centroid to edge), radius ratio, box height, box width, and fractal dimension. The large multidimensional datasets (*n*90,000-210,000 particles/sample) were analyzed using an open-source statistical package; the results from the multivariate statistical methods will be presented. Initial statistical results from the pilot study, which included only 23 Al powders, showed classification success rates ranging from 81%-94%, depending on particle size range.

Aluminum Powder, Particle Micromorphometry, Automated Stage Analysis

B48 Identification and Separation of Nitrate Esters Using Both Liquid Injection Gas Chromatography/Mass Spectrometry (GC/MS) and Total Vaporization Solid Phase Microextraction (TV-SPME) GC/MS

Jordan Ash, BA, 1435 Stadium Way, Apt 2101, Indianapolis, IN 46202; and John V. Goodpaster, PhD, FIS Program, IUPUI, 402 N Blackford Street, LD 326, Indianapolis, IN 46202*

After attending this presentation, attendees will understand the value and need for a singular method that allows for the identification and separation of various nitrate esters found on exploded devices. TV-SPME/GC/MS is a new technique that has several benefits over traditional liquid injection.

This presentation will impact the forensic science community by providing a singular method of analysis for nitrate esters, saving both time and money as well as increasing sensitivity.

Given that most laboratories utilize a liquid injection procedure, a method has been developed using this technique; however, a novel technique based upon TV-SPME/GC/MS has also been used with great success in identifying compounds of interest. This novel technique has the inherent benefit of having a much lower limit of detection and can therefore allow for identification with less sample preparation and small sample sizes. This is of great interest as the explosive used in a device can be determined from smaller samples recovered from a post-blast site.

The detection and identification of post-blast residues is an important part of an explosives investigation; however, various methods must be used in determining the type of explosive that was used in the device. This study sought to determine if a single method could be found to separate and identify the various nitrate ester explosives as well as their degradation products. It was found that GC/MS could be used to differentiate a number nitrate esters such as Nitroglycerin (NG), Ethylene Glycol Dinitrate (EGDN), Pentaerythritol Tetranitrate (PETN), Erythritol Tetranitrate (ETN), Pentaerythritol Trinitrate (PETriN), 1-nitroglycerin, 2-nitroglycerin, 1,2-dinitroglycerin, and 1,3- dinitroglycerin.

Nitrate esters fragment identically within a mass spectrometer; therefore, having a true separation using a GC program prior to entering the MS is vital. Several variables were investigated using liquid injection, such as inlet temperature, flow rate, and inlet temperature ramp speed. In addition to liquid injection, a novel method was developed using TV-SPME/GC/MS. TV-SPME is a process that is most akin to immersion SPME. In immersion SPME, a two-phased system is present between the liquid containing the analyte and the SPME fiber. In TV-SPME, heat is used to drive all of the analyte into the gaseous phase. By taking a small amount of liquid that can be totally vaporized into the gaseous phase, one is able to create a two-phase environment between the analyte in the gaseous phase and the SPME fiber. This has the benefit of increasing sensitivity and decreasing sample preparation. Throughout this study, the following parameters were optimized: fiber type, incubation temperature, and multi-stage inlet temperature ramp. This method was able to separate and identify PETN, EGDN, NG, and ETN and the detection limits for these compounds was as low as 50 parts-per-trillion. Post-blast debris from the initiation of PETN-based plastic explosives was also analyzed.

Nitrate Esters, Explosives, SPME

B49 High-Sensitivity Detection and Separation of High Explosives in Environmental Samples

Christopher M. Rollman, BS, George Washington University, 2100 Foxhall Road, NW, Somers Hall, L14, Washington, DC 20007; Karen A. Brensinger, MFS, George Washington University/U.S. Army Forensic Toxicology Drug Testing Lab, 2490 Wilson Street, Fort Meade, MD 20755; Christine Copper, PhD, United States Naval Academy, 572 Holloway Road, Annapolis, MD 21402; Ashton Genzman, BS, United States Naval Academy, 572 Holloway Road, Annapolis, MD 21402; Jacqueline Rine, BS, United States Naval Academy, 572 Holloway Road, Annapolis, MD 21402; Ira S. Lurie, PhD, George Washington University, Dept of Forensic Science, 2100 Foxhall Road, NW, Somers Hall, Lower Level, Washington, DC 20007; and Mehdi Moini, PhD, George Washington University, Dept of Forensic Sciences, 2100 Foxhall Road, NW, Washington, DC 20007*

The goal of this presentation is to discuss a new technique to detect high explosives in environmental samples using Micellar Electrokinetic Chromatography/Mass Spectrometry (MEKC/MS).

This presentation will impact the forensic science community by examining how forensic chemists can use this rapid and highly sensitive method to separate and identify high explosives in contaminated sand, soil, and water samples.

High explosives constitute the majority of modern military and industrial explosive applications. Because of their wide use, their environmental footprint is becoming an issue. Therefore, identification of high explosives in soil and water is important. Currently, Gas Chromatography/Mass Spectrometry (GC/MS) and High-Performance Liquid Chromatography/Mass Spectrometry (HPLC/MS) are the preferred techniques for the analysis of explosives, yet both have drawbacks. GC/MS is not suitable for the analysis of thermally labile compounds, which include some high explosives, while HPLC/MS lacks sensitivity due to low ionization efficiency of high explosives under negative ionization. Therefore, a selective and sensitive method for the separation and detection of high explosives is desirable. In collaboration with the United States Naval Academy, a novel MEKC/MS technique was developed for the detection of high explosives using a complexation reagent.

Analyses were performed using a Beckman Coulter ProteomeLab™ PA 800 sheathless Capillary Electrophoresis (CE) interfaced to a Thermo™ Orbitrap Elite™ high resolution MS using underivatized fused-silica capillaries (20µm I.D., ~100cm in length) with a porous tip. Electrospray voltage was 1.1kV and the mass spectrometer heated capillary was 150°C. Analyses were performed using a Perfluorooctanoic Acid (PFOA) ammonium salt as a background electrolyte. All samples were injected using pressure (1psi for 4s) and a separation voltage of 25kV was used. Compounds were detected in negative ion mode as a complex with PFOA. Explosive samples from the United States Army Chemical, Biological, Radiological, Nuclear, and Explosives (CBRNE) Analytical & Remediation Activity Mobile Expeditionary Laboratory have been obtained, extracted, and analyzed using this newly developed MEKC/MS method.

High explosives that formed complexes with PFOA included RDX, HMX, tetryl, and PETN. Also, amino-dinitrotoluene formed a complex with PFOA. Other nitroaromatics were detected as molecular ions. The five explosives which formed complexes with PFOA had detection limits in the high parts-per-billion range and linear calibration responses over two orders of magnitude. The technique was successfully applied to the quantitative analysis of high explosives in sand samples.

Using PFOA as a background electrolyte, high explosives from contaminated sand samples could be separated and detected with high sensitivity.

High Explosives, Environmental Samples, CE/MEKC/MS

B50 Application of a Linear-Targeted Approach in Multiplex Amplification of the Mitochondrial Genome

Maureen Hickman, MS, Western Carolina University, 111 Memorial Drive, NSB 231, Cullowhee, NC 28723; and Kelly Grisedale, PhD, Western Carolina University, 111 Memorial Drive, NSB 231, Cullowhee, NC 28723*

After attending this presentation, attendees will have a better understanding of a linear-targeted approach designed to increase template DNA in low copy samples. Moreover, implementation of the linear approach in multiplex amplification and Massively Parallel Sequencing (MPS) of the whole mitochondrial genome will be presented.

This presentation will impact the forensic science community by providing an avenue to maximize data recovery from low quality samples.

In cases where limited or degraded nuclear DNA precludes the use of capillary electrophoresis to obtain a reliable Short Tandem Repeat (STR) profile, forensic scientists often turn to the mitochondrial genome due to its higher copy number per cell. The emergence of MPS in forensic science has enhanced the capability to recover extensive sequence information, thereby increasing the power of discrimination in mitochondrial DNA (mtDNA). Furthermore, MPS provides the breadth and depth of coverage necessary to detect low-level heteroplasmic variants across the mitochondrial genome (mtGenome) with a relatively small initial DNA input.

Though mtDNA may afford a more viable option when sample quality is questionable, there are instances where DNA yield remains too low to deliver a reliable haplotype. Polymerase Chain Reaction (PCR) -based techniques have been successful in increasing DNA yield of low-copy number samples; however, due to the exponential nature of PCR, increasing PCR cycle numbers can exacerbate stochastic sampling effects, especially in diploid nuclear DNA.[1,2] One method suggested to help alleviate this problem is targeted non-exponential amplification.[3] A Single Strand Extension Assay (SSEA) seeks to boost copy number prior to traditional analysis by employing a linear-targeted amplification approach. Briefly, samples are divided and amplified separately in two reactions with either a forward or reverse primer. Similar to PCR, SSEA includes denaturation, annealing, and extension steps, but with either forward or reverse primer in the reaction, only one additional copy of the product is produced after each cycle. Following SSEA, products from each reaction are pooled and sufficient template DNA is available for subsequent PCR analysis. Due to its haploid nature, the mtGenome provides an optimal target for evaluating the utility of SSEA, as the stochastic effects associated with diploid genomes (e.g., heterozygote imbalance, allele drop-out) will be excluded.

The utility of SSEA on mtDNA was initially tested for the hypervariable region. Commercially available DNA (HL-60) and DNA isolated from telogen hairs were diluted to low-template levels and amplified in separate forward and reverse reactions. Amplification success was evaluated on the Agilent® 2100 Bioanalyzer and absence of primer dimer was confirmed. Forward and reverse products were then combined and subjected to a second round of traditional PCR, prepared for MPS using Nextera® XT kit, and run on Illumina® MiSeq®. Preliminary results indicate that performing SSEA on low-template samples prior to traditional PCR provides sufficient target DNA for MPS.

To further test the effectiveness of SSEA, a previously developed low-volume multiplex PCR assay that amplifies ~350bp-650bp fragments around the mtGenome was employed. The multiplex assay has successfully amplified telogen hair and bone samples with minimal DNA input (fewer than 1,500 copies) and average MPS coverage ranges from 11,530 to 23,239. To implement SSEA using the multiplex assay, primers from either the heavy or light strand were carefully selected and extension performed separately for each of three multiplex reactions. Heavy and light strand products were then combined and subjected to a second round of traditional PCR, prepared for MPS using Nextera® XT kit and run on Illumina® MiSeq®.

The SSEA combined with the low-volume multiplex assay provides a viable option for maximizing data recovery from low-template DNA samples. Future research will focus on applying SSEA to other types of forensically relevant samples as well as evaluating SSEA performance in nuclear DNA using MPS.

Linear Amplification, Mitochondrial Genome, Multiplex Amplification

B51 Assessment of Low-Level Error in Massively Parallel Sequencing (MPS) Data Sets Generated Using the Illumina® MiSeq® Platform and Synthesized Human Mitochondrial DNA Oligonucleotides

Brittania J. Bintz, MSc, 111 Memorial Drive, NSB 231, Cullowhee, NC 28723; Timothy Driscoll, PhD, West Virginia University, Dept of Biology, Life Sciences Building, PO Box 6057, Morgantown, WV 26506; and Mark R. Wilson, PhD, Western Carolina University, Dept of Chemistry/Physics, Forensic Science, Cullowhee, NC 28723*

After attending this presentation, attendees will better understand ongoing validation studies designed to assess the accuracy, precision, and reproducibility of the Illumina® MiSeq® sample preparation workflow and sequencing chemistry in human mitochondrial DNA (mtDNA) analysis.

This presentation will impact the forensic science by illustrating that the use of MPS technologies in forensic casework is eminent. Therefore, dissemination of information related to MPS validation studies is an important step in showing general acceptance of the method by the scientific community and, ultimately, the courts.

MPS sequencing methods are proving to be particularly well-suited for mtDNA analysis and may provide forensic analysts with a powerful tool that enables deconvolution of mtDNA mixtures or accurate quantitation of low-level heteroplasmy; however, some effort remains in validating the systems for such analyses.[1-5] Several MPS platforms are commercially available, each with a unique library preparation strategy and sequencing chemistry that may give rise to method-specific errors. Furthermore, since many alignment and variant-calling algorithms are available, there is limited consistency in the use of data analysis methods employed. Finally, no studies have been performed to determine what depth of coverage is required to confidently call a true biological low-level variant above the level of method-generated noise.

This study seeks to identify error rates associated with each step in the Illumina® MiSeq® MPS workflow. Initially, synthetic oligonucleotides with sequences matching the revised Cambridge Reference Sequence (rCRS) Hypervariable (HV) regions I and II of the human mtDNA genome were purchased from Life Technologies™. Each oligonucleotide was designed to contain Illumina® sequencing primers, flow cell adapters, and multiplexing indices on either end to enable direct sequencing without additional preparation. The oligonucleotides were also designed to contain restriction enzyme cut sites between the target sequence and Illumina® modifications. This design allowed for removal of Illumina® modifications so the same sample could be prepared for sequencing using the recommended library preparation strategies. Each synthetic oligonucleotide was sequenced: (1) directly with no additional preparation; (2) after Illumina® Nextera® XT library preparation; and, (3) after triplicate PCR amplification with target-specific primers followed by Nextera® XT library preparation. Samples prepared with treatments B and C were sequenced in duplicate to enable assessment of intra-run variation. Sequences were generated on the Illumina® MiSeq® with a v2 300-cycle run kit. Resulting sequence data was aligned to the rCRS using BWA-MEM alignment algorithm.[6] Variant calling was performed with SAMtools 0.1.19 using the consensus-caller and a maximum depth of 1,000.[7]

Error rates obtained from all sample treatments were compared to identify differences at each step in the library preparation workflow. Overall, data quality decreases as the sequencing progresses with late cycle basecalls being lower in quality than early cycle calls. Additionally, reverse reads tend to have lower average quality scores than forward reads. Overall, there does not appear to be a discernable effect from sequencing chemistry or PCR amplification during sample preparation. Ultimately, this experimentation sets the groundwork for validation of the Illumina® MiSeq® MPS system for mtDNA analysis in forensic casework.

B52 Evaluation of Collection Protocols for the Recovery of Biological Samples From Crime Scenes

Dina Al Oraer, BS, UCLAN, 60 Victoria Mansions, Navigation Way, Preston, Lancashire PR2 2YY, UNITED KINGDOM*

After attending this presentation, attendees will understand how to improve the efficacy of the processes of collection and storage up to the point where the evidential material is received at a laboratory. Included in this presentation will be the effect of the environmental factors on degradation of collected samples before they reach the laboratory.

This presentation will impact the forensic science community by providing a clear indication of best practices in post-collection sample handling while in transit to the laboratory and may form the basis of future sample handling protocols.

The main focus in forensic genetics in the past 20 years has been to increase efficiency of the extraction and identification of DNA from a wide variety of evidence and to improve DNA profiling technology by making it more sensitive and robust. Much effort has been put into the improvement of DNA extraction and analysis techniques. Whichever technology is used, the precursors to extraction and analysis are the sample collection, handling, and storage. Collection, preservation, and storage of DNA are critical factors in ensuring reliable forensic genetics. These steps can have a fundamental impact on the quality of the sample and the resultant DNA profile; however, the methods used to recover DNA evidence from crime scenes have seen little development. This study proposed to improve the efficacy of the collection and storage up to the point where the evidential material is received at a laboratory.

Sample collection is one of the most critical steps in DNA profiling. Great care has to be taken to avoid contamination and degradation of the samples and the consequential spoiling of evidence. With the correct protocols, sample preservation in the laboratory can be carefully controlled, but this is more difficult in the field or when transporting from the scene of the crime to the laboratory. The preservation of the evidence is increasingly important when the environmental conditions are extreme and the time between collection and receipt by the laboratory is extended.

The collection of biological evidence with swabs using ultrapure water as a wetting agent was compared to the use of a propriety detergent-based wetting agent. The recovery of biological material using the detergent-based wetting agent is only marginally better than ultrapure water, but the post-collection stability is greatly improved. DNA degradation can be seen after approximately 6h at room temperature when using ultrapure water as the wetting agent. The detergent-based solution stabilized DNA for up to 48h, even when the temperature is increased to 37°C. The impact of this is likely to be limited in circumstances in which crime scene evidence can be kept at low temperatures until it reaches the laboratory; however, in contexts where this is problematic, the modified method for collection could have a large impact on the preservation of forensic evidence before it reaches the laboratory. The result of this initial research confirms that post-collection environmental factors have a significant impact on DNA recovery rates. Further research will be required to confirm and extend these results. Other substrates may be considered. This research should give a clear indication of best practices in post-collection sample handling while in transit to the laboratory and may form the basis of future sample handling protocols.

Forensic Genetics, Biological Samples, DNA

B53 Single Molecule Forensic DNA Characterization With Laser-Induced Nanopore Heating

Sarah J. Seashols Williams, PhD, Virginia Commonwealth University, Dept of Forensic Science, PO Box 843079, Richmond, VA 23284-3079; Christopher Angevine, BS, Virginia Commonwealth University, Dept of Physics, 701 W Grace Street, Box 842000, Richmond, VA 23284-2000; Nicole Auka, Virginia Commonwealth University, Dept of Forensic Science, 1015 Floyd Avenue, Box 843079, Richmond, VA 23284-3079; and Joseph E. Reiner, PhD, Virginia Commonwealth University, Dept of Physics, 701 W Grace Street, Box 842000, Richmond, VA 23284-2000*

After attending this presentation, attendees will recognize that pre-analysis sample characterization could be a useful tool in the forensic workflow. Attendees will be briefed on a novel method of DNA analysis using nanopore sensing and its potential applications to forensic science.

This presentation will impact the forensic science community by proposing a novel method for pre-analysis mixture deconvolution and promote more research toward that goal.

Forensic DNA analysis relies on techniques that can yield incomplete or very complex results, based on the number of people contributing to the sample. This creates a need to develop rapid screening methods that provide previews of the genotype(s) in the sample, especially given the impending costly and time-intensive high-throughput sequencing revolution of forensic human identification. Determining the number of amplified fragments in solution from a single amplified Short Tandem Repeat (STR) locus can indicate the number of individuals contributing to the evidence. A new approach has been identified that could provide this "preview genotype" of the sample, utilizing laser heating in conjunction with nanopore-based resistive pulse sensing to identify the number of differently sized DNA fragments in a given sample.

Nanopore sensing is a well-established technique that utilizes the Coulter-counting principle to detect single molecules. Briefly, an applied transmembrane voltage drives ionic current through an isolated pore and individual DNA molecules are driven into the pore, thus reducing the flow of current and giving rise to short-lived current blockades. The magnitude and duration of these blockades can be analyzed to infer information about the size of the DNA molecules. Nanopore-DNA studies showed that the time for a single stranded (ssDNA) molecule to move through an alpha hemolysin pore scales linearly with the number of bases. Given the short time that ssDNA spends moving through the pore (»2-3µs/base), it is difficult to distinguish between different, but similarly sized, DNA molecules.

This presentation will describe the efforts taken to address this issue through modification of the nanopore sensor with the addition of infrared laser heating and the study of double stranded DNA (dsDNA). Studies showed that heating the solution in and around a pore facilitates unzipping of the dsDNA and this process yields DNA pore transit times that scale exponentially with the length of the DNA molecules. This phenomenon was consistent over hundreds of replications. This suggests a way to clearly distinguish between current blockades from different-sized molecules, which could lead to a rapid and accurate technique for prioritizing samples for further forensic analysis. The results show that heat-induced residence time discrimination was enhanced over a range of DNA sizes up to 70nt. This discrimination also enables the relative proportion of different-sized DNA fragments in a binary mixture to be distinguished. Future efforts will expand these results to DNA sizes on the order of the commonly used forensic STR "mini" loci (60-100 nucleotides) with the goal of demonstrating mixture ratio analysis on samples containing alleles differing in size by 4nt-8nt.

Mixture Deconvolution, Nanopore, Forensic DNA

B54 Forensic Application of Massively Parallel Sequencing (MPS) With the Ion Torrent™ Multiplex Mitochondrial Genome Panel and Hi-Q™ Sequencing Chemistry

Jennifer D. Churchill, PhD, UNTHSC, 3500 Camp Bowie Boulevard, CBH-250, Fort Worth, TX 76107; Jonathan King, MS, 3500 Camp Bowie Boulevard, Fort Worth, TX 76107; Joseph P. Chang, BS, Thermo Fisher Scientific, 180 Oyster Point Boulevard, South San Francisco, CA 94080; Sharon C. Wootton, PhD, 180 Oyster Point Boulevard, South San Francisco, CA 94080; Chien-Wei Chang, PhD, Thermofisher Scientific, 180 Oyster Point Boulevard, South San Francisco, CA 94080; Robert Lagacé, BS, Thermo Fisher Scientific, 180 Oyster Point Boulevard, South San Francisco, CA 94080; and Bruce Budowle, PhD, UNT Health Science Center, Forensic & Investigative Gen, 3500 Camp Bowie Boulevard, EAD 310, Fort Worth, TX 76107*

After attending this presentation, attendees will better understand a variety of the latest developments used in MPS on the Ion PGM™ platform such as the introduction of a new sequencing chemistry and the creation of a new forensically relevant marker system.

This presentation will impact the forensic science community by providing information and current progress on MPS that will support its eventual transition into forensic laboratories.

While still considered the "gold standard" of DNA typing in forensic laboratories, Capillary Electrophoresis (CE) -based technologies face limitations in scalability and throughput. Due to these limitations, sequencing beyond hypervariable regions I and II of the mitochondrial genome is rarely attempted in forensic laboratories. Advancements and developments in MPS technologies offer a strong alternative to the CE-based process, and the Ion PGM™ provides a promising MPS platform for forensic analysis with a read length, sensitivity of detection, and throughput that should incorporate well into forensic laboratories; however, transition of MPS technologies into forensic laboratories requires an efficient workflow, sequencing chemistry that produces robust and accurate data, and forensically relevant marker systems.

The Ion Torrent™ Hi-Q™ sequencing chemistry was evaluated to determine whether it had an effect on sequence quality. The whole mitochondrial genome of 31 individuals was sequenced with the original and new Hi-Q™ sequencing chemistries. Haplotype calls, coverage, strand balance, noise, and sequence quality through homopolymeric regions (i.e., deletion ratios) were evaluated for both data sets. Results were concordant between the sequencing chemistries for haplotype calls, coverage, strand balance, and noise level results; however, the Hi-Q™ sequencing chemistry showed an improved ability to sequence through homopolymeric regions, which was illustrated by a decrease in deletion ratios through these regions compared with the original sequencing chemistry.

Additionally, using the new Hi-Q™ sequencing chemistry, a comprehensive multiplex short amplicon panel was developed that spans the entire mitochondrial genome. This panel is currently comprised of two multiplexes with 81 primer pairs each that generate amplicons ≤175bps in length, making it well-suited for analysis of challenged samples. When used with the Ion Chef™, the workflow is sufficiently robust to support analysis of the entire mitochondrial genome. Thirty-one individuals were sequenced with this mitochondrial multiplex panel and sequence concordance, coverage, and strand balance were used to evaluate the quality and reliability of the data produced. Analysis showed that haplotype calls for these samples were concordant with whole mitochondrial genome data generated by long Polymerase Chain Reaction (PCR), coverage ranged from 307X to 8,583X, and strand balance illustrated reads were generated from both strands of the DNA. These results indicate robust and accurate data were generated. A serial dilution was completed for three individuals by varying the amount of input DNA from 1ng to 1pg and results illustrated the sensitivity of detection of this mitochondrial multiplex panel. Finally, successful analysis of historical skeletal remains with this mitochondrial multiplex panel demonstrated the great potential this panel offers for analysis of challenged samples. Overall, the quality of the data generated in this study supports the promising potential for incorporating whole genome mitochondrial analysis on the Ion PGM™ system.

Massively Parallel Sequencing, Forensic DNA Typing, Mitochondrial DNA

B55 From Fragment Isolation to DNA Amplification: A Detailed Protocol for Using Plant and Insect Material in Forensics

Megan L. Jackson, BS, 1 Joplin Court, Stafford, VA 22554; Kelly A. Meiklejohn, PhD, ORISE/FBI Laboratory, 2501 Investigation Parkway, Quantico, VA 22204; Jack Hietpas, PhD, FBI-ORISE, 2501 Investigation Parkway, Quantico, VA 22135; Libby A. Stern, PhD, FBI Laboratory - CFSRU, 2501 Investigation Parkway, Quantico, VA 22135; and James M. Robertson, PhD, CFSRU, FBI Laboratory, 2501 Investigation Parkway, Quantico, VA 22135*

After attending this presentation, attendees will be aware of a tested protocol for the isolation, extraction, and amplification of DNA from soil biological fragments.

This presentation will impact the forensic science community by providing an alternative to bulk meta-genomics for the analysis of biological fragments recovered in soil samples.

In the current era of massively parallel sequencing, there has been an influx of studies documenting the biological diversity in soil samples using a bulk metagenomic approach. Insect and plant fragments have been collected for hundreds of years and more recently documented based on their geographic region by the National Bureau of Agriculturally Important Insects and the United States Department of Agriculture. Within a collected sample, there can be substantial diversity in the biological fragments. In most cases, it is not possible to classify them using morphology for taxonomic identification; however, by using conserved primers targeted to specific groups of organisms such as insects, plants, fungi, and bacteria, individual taxa can be amplified and sequenced to provide a detailed picture of the biological community. Although a metagenomic approach facilitates the collection of large amounts of data from small and even very degraded samples, the current usefulness of this technique mainly lies with cross-sample comparisons; the Operational Taxonomic Units (OTUs) identified are compared among samples to determine whether it is likely they came from the same source/location. Species-level taxonomic identification is not possible using this approach, but such data could prove useful for soil geoattribution considering biological organisms only inhabit specific ecosystems.

A molecular-based approach may provide a more accurate and reliable tool for species identification. One commonly used technique for molecular identification is DNA barcoding. DNA barcoding is based on the notion that there is substantial variation at the DNA level among organisms to permit discrimination (i.e., each species on Earth will have its own unique barcode sequence). As DNA is embedded in every cell, a DNA barcode approach can be used to identify insect and plant fragments found within a soil sample. The current project was focused on developing a protocol to successfully isolate DNA from *individual* biological fragments commonly recovered from soil samples. To facilitate taxonomic identification of the samples, the appropriate DNA barcoding region was amplified according to established protocols of expert researchers in the field.[1]

This presentation will outline the details of the protocol including: (1) fragment isolation, washing, and documentation (photography and weighing); (2) extraction of the total genomic DNA; (3) determination of the DNA quality in each sample; (4) Polymerase Chain Reaction (PCR) optimization for the amplification of the insect (*CO1*) and plant (*matK* and *rbcL*) barcoding regions from a broad range of samples; and, (5) techniques used to screen PCR amplicons prior to sequencing.

Individual Biological Fragment, DNA Extraction, PCR

B56 Investigation of the Genomics of Cannabinoid Biosynthesis in *Cannabis Sativa*

Robert W. Allen, PhD, Oklahoma State University, Center for Health Sciences, 1111 W 17th Street, Tulsa, OK 74107-1898; Lindsey N. Allen, BS, Oklahoma State University, Center for Health Sciences, 1111 W 17th Street, Tulsa, OK 74107; Jane Ketner Pritchard, BS, 1111 W 17th Street, Tulsa, OK 74107; Jun Fu, PhD, 1111 W 17th Street, Tulsa, OK 74107; Rachel Wellendorf, BS, Oklahoma State University, 1111 W 17th Street, Tulsa, OK 74107; and Lindsey Yoder, MSFS, Oklahoma State University, 1111 W 17th Street, Tulsa, OK 74107*

After attending this presentation, attendees will: (1) be introduced to the biosynthetic pathway leading to the production of cannabinoids; (2) correlate the biosynthesis of cannabinoids with the underlying molecular characteristics of the genes encoding the enzymes that synthesize cannabinoids; and, (3) relate the molecular genetics of enzymes involved with cannabinoid biosynthesis with the potential to manipulate this species genetically to produce cannabinoids with medicinal properties.

This presentation will impact the forensic science community by contributing to a newer understanding of how variability at the DNA level in marijuana can significantly impact the chemical composition of this plant that holds promise as a source of natural medicines.

Currently, there are 23 states and the District of Columbia that have legalized the medical use of marijuana and its chemical products.[1] In addition, four states and the District of Columbia have legalized the recreational use of the plant as well.[1] The increasing legal use of marijuana and its products has stimulated research into the pharmacological benefits of the principal chemicals of interest produced by cannabis strains and also the biosynthesis of these compounds known collectively as cannabinoids. Two principal cannabinoids, delta-9-Tetrahydrocannabinol (THC) and Cannabidiol (CBD) have received the greatest attention to date; however, more than 60 cannabinoid compounds have been identified in cannabis.[2] Paralleling interest in the chemical composition of cannabis has been an interest in the genetics/genomics of the plant.[3]

The research discussed here has concentrated on two of the biosynthetic enzymes involved in the production of two of the principal cannabinoids with known medicinal effect, THC and CBD. The enzymes THC synthase and CBD synthase, respectively, are responsible for the conversion of Cannabigerolic (CBG) acid into the acidic forms of THC or CBD, which when heated, spontaneously become decarboxylated to the mature drug forms. The genes encoding THC synthase and CBD synthase are more than 80% homologous in sequence and exist in the genome as intronless genes of 1,635 basepairs.[4]

The THC and CBD synthase genes present in numerous seized cannabis samples were subjected to next generation sequencing on an Ion Torrent™ platform. Findings from these studies have indicated that the THC synthase and CBD synthase genes exist in cannabis in active and inactive forms based upon the Single Nucleotide Polymorphisms (SNPs) present within the coding sequence. In the case of the THC synthase gene, 30 SNPs have been detected within the 1,635bp coding sequence and behave as a "haplotype." In other words, these SNPs travel together as a unit in different plants. It has been reported that some THC synthase genes are inactive as a result of SNP mutations that create stop codons or alter the amino acid sequence significantly. In hemp (which does not synthesize THC), this inactive haplotype is carried by both chromosomes, whereas plants producing THC genotype are either heterozygous for the inactive haplotype or homozygous for the active haplotype. Sequencing results showed that for CBD synthase, there were as many as 90 SNPs detected in the coding sequence for the gene. Future work involves obtaining additional plant materials rich in CBD to distinguish between the active and inactive haplotypes for the CBD synthase gene. It has been observed that seized marijuana may not exhibit appreciable amounts of CBD as would be expected from marijuana produced for illicit use even though it contained 3%-10% (by weight) THC.

B57 Current Efforts on Developmental Aspects of Forensic Botany in Brazil

Renato T. Ferreira de Paranaiba, BA, Brazilian Federal Police, Lab. de Genética Forense, INC, Polícia Federal, SAIS Quadra 07 Lote 23, Brasília, Distrito Federal 70610200, BRAZIL; Carlos B. Carvalho, PhD, Sqs 212 Bloco K Apt 207, Brasilia, Distrito Federal 70275110, BRAZIL; Jorge Freitas, PhD, Departamento de Polícia Federal, Laboratório de Genética Forense, SAIS Quadra 07 Lote 23,, Brasília 70610200, BRAZIL; Gustavo Chemale, PhD, Departamento de Polícia Federal, Laboratório de Genética Forense, SAIS Quadra 07 Lote 23, Brasília 70610200, BRAZIL; and Katia Michelin, MSc, Departamento De Polícia Federal, Laboratório De Genética Forense, Sais Quadra 07 Lote 23, Brasília 70610200, BRAZIL*

After attending this presentation, attendees will better understand the current efforts of a forensic science subject that is less-developed, particularly in Brazil.

This presentation will impact the forensic science community by presenting the singularities of the forensic botany cases which will be discussed.

Botany is an area of study somewhat less developed than other forensic sciences. In fact, it can be said that botany is a promising subject of applied studies in criminal investigation. Plant DNA barcoding has emerged as a powerful and reliable tool for routine applications in forensic science. Furthermore, its application to plant species identification has provoked a renaissance for the use of taxonomy in basic science research.

Despite relevant initiatives and promised efforts by some groups, forensic botany in Brazil remains in its infancy when considering the advances of DNA technology. This is particularly surprising when the vast biodiversity of Brazil is considered; however, the application of plant DNA testing would have an impact beyond Brazil, as there are cases of plant materials suspected to be illicit that find their way into other countries. It would be useful to have a method to identify the same species in different places in an attempt to determine their origins. Demands addressed to forensic botany remain mostly unsolved; perhaps DNA testing could be helpful.

Cannabis sativa, *Salvia divinorum*, and *Lophophora williansii* are all classified as controlled plants under Brazilian legislation and all are prohibited. Punishment for trafficking may be a sentence of up to 15 years in prison.

Identification of these plant materials is conducted using morphological observation based on specific features in addition to chemical tests to identify the presence of specific compounds. More recently, the intrinsic limitations of these techniques are giving rise to the opportunity of using DNA analysis, especially due to the advantages of this technology.

Seeds or leaves from plant material were pulverized and DNA was extracted using commercial kits. Universal Polymerase Chain Reaction (PCR) primers were used that would amplify four DNA regions (*matK*, *rbcL*, Intergenic Spacer (IGS)_trnL-trnF, and Internal Transcribed Spacer (ITS)) for most land plants. PCR amplifications of the DNA were performed in a 9700 Applied Biosystems® thermal cycler. PCR products were checked using a 1% agarose gel electrophoresis and ultraviolet detection by spectrophotometer and purified with the Exonuclease I and Shrimp Alkaline Phosphatase (SAP). Sequencing of the PCR products was performed using both the forward and reverse primers in PCR amplification and the BigDye Terminator 1.1 kit. After purification, the cycle sequencing products were detected by an Applied Biosystems® 3130 Genetic Analyser with Data Collection and Sequencing Analysis software. Sequences were assembled and evaluated with the SeqScape® software and were compared to those present in on-line databanks (Genbank® and Barcode Of Life Data Systems (BOLD) v3). Further analysis, including phylogenetic trees, was performed on Mega 6 software.

The kingdom Plantae is a very complex universe. Forensic botany is taking its earliest yet very important steps and its development in Brazil is even more recent than in other countries. The first experiences of a Brazilian forensic DNA laboratory with forensic botany are reported here; three cases regarding this matter are described along with their key points. Finally, an interesting point regarding the DNA extracting method is discussed. Plant DNA barcoding may fit well in the automated technology already available at many forensic laboratories. Adding plant DNA testing may be easier based on past experience with implementing techniques for forensic human DNA.

Plant, DNA, Barcoding

B58 Inferring Geographical Origin of Forensic Evidence Via DNA Barcodes

Jack N. Lane, MS, Bode Technology, 10430 Furnace Road, Ste 107, Lorton, VA 22079; Michael N. Parsons, MS, 10430 Furnace Road, Ste 107, Lorton, VA 22079; and Donia Slack, MS, 10430 Furnace Road, Ste 107, Lorton, VA 22079*

After attending this presentation, attendees will understand the potential applications of using the DNA signature of regional plants for investigative leads and the ability to attribute plant material to a point of origin. Modern databases and sequencing technologies allow for increasingly more accurate determination of the geographical origin of plant material when only a minimal amount of plant debris may be available.

This presentation will impact the forensic science community by offering new insight into the effectiveness of plant barcoding for a forensic application of attributing a region of interest to potential evidence. Attendees will also better understand the performance of specific barcoding genes in various geographical areas.

During a forensic investigation, a wide variety of evidence types may be presented to an investigator, each offering a unique element or perspective to a crime. One particular type of evidence that may often be underutilized during investigation is plant debris. Plant material, when exploited for forensic leads, can assist in generating source attribution of evidence matter, resulting in inference of location and/or routes of travel. Forensic botany has traditionally relied on identification through morphological assessment of plant material. These methods often require well-preserved plant specimens or multiple portions of a plant that may not be available to the investigator. To overcome the limitations of traditional plant identification methods, it was proposed that sequence analysis of the widely accepted plant barcoding gene for ribulose bisphosphate carboxylase (*rbcL*) be used to identify plant specimens from mock evidentiary samples. Mock evidentiary samples were prepared using morphologically identified plant material collected from three specific locations in defined areas of the east coast of the United States: the Northeast, Mid-Atlantic, and Southeast regions. After collection, specimen DNA was extracted using the MoBio PowerPlant® Pro DNA extraction kit. The resulting mixture was sequenced on the Roche® 454 GS Junior next generation DNA sequencing platform. Using the CLC Genomics software, unique sequences were identified and used to query two existing plant barcode databases including Genbank® and Barcode Of Life System (BOLD). The degree of success was determined by assessing the accuracy of the range of distribution to the known origin of the mock evidentiary sample's constituents. By exploiting these ubiquitously used plant databases, this technique bypasses the need for expensive and laborious *de novo* databasing of plant genomes for a specific forensic application.

Results of the study indicate that *rbcL* universal primers can be utilized on the Roche® 454 GS Junior to sequence plant mixture samples. The geographical origins for two of the three collection regions were successfully identified using heat maps that illustrate the presence of each identified plant specimen within each collection region. Although the heat maps demonstrated a fair amount of overlap, the Northeast and Southeast regions showed clear delineations of attribution which allowed for the plant material to be sourced back to a corresponding point of origin. The Mid-Atlantic region could not be attributed to a plant mixture sample, as the sample's constituents generated vast native geographical ranges that could not confidently be attributed to a particular area of isolation. Thus, this research demonstrated that successful and confident source attribution of evidentiary plant debris is strongly reliant on the genetic variation of the sample and the representation of plants with a limited geographical distribution. It is important to note that the data reflect the success rate of only a single proposed barcoding gene, *rbcL*. Therefore, this technique may better serve the forensic community if supplementary barcoding genes are exploited to generate enhanced sequencing success and downstream plant identification.

Geosourcing, DNA Barcoding, Next Generation Sequencing

B59 Botanical DNA Evidence in a Case of Robbery and Property Crime: Application of High Resolution Melting Analysis of *Triticuma Aestivum* L. Grains

Alejandra Figueroa, BSc, Policia de Investigaciones de Chile, Aldunate 620, Temuco, CHILE; Jaime H. Solano, PhD, Universidad Católica De Temuco, Avenida Rudecindo Ortega 02950, Temuco 4813302, CHILE; Leonardo I. Anabalon, Universidad Católica De Temuco, Avenida Rudecindo Ortega 02950, Temuco 4813302, CHILE; and David A. Gangitano, PhD, Sam Houston State University, 13906 Paradise Valley Drive, Houston, TX 77069*

After attending this presentation, attendees will understand the importance of the use of genetic botanical evidence in casework.

This presentation will impact the forensic science community by increasing fundamental understanding of the application of real-time Polymerase Chain Reaction (PCR) technology and DNA barcoding to the discriminatory analysis of plants.

Forensic botany is an emerging discipline that has evolved rapidly during the past few years. Botanical evidence is usually found at crime scenes and sometimes is the only available element for criminal investigations in cases where other evidence is absent. Different molecular techniques have been applied to analyze botanical evidence including Random Amplified Polymorphic DNA (RAPD), Amplified Fragment Length Polymorphism (AFLP), Inter-Simple Sequence Repeat Amplification (ISSRs), chloroplast and mitochondrial DNA, and Short Tandem Repeats (STRs). In recent years, research has been focused on DNA barcoding to determine the species of different organisms through sequencing of conserved DNA regions such as Cytochrome C Oxidase I (COI) or Internal Transcribed Spacer (ITS). Another application of DNA barcoding is the use of real-time PCR combined with High Resolution Melting (HRM) analysis to discriminate specific conserved DNA regions of closely related botanical species. For melting temperature (Tm) determination, an intercalating fluorescent dye is added to the real-time PCR reaction and a derivative melting curve is generated. Distinct nucleotide sequences of a conserved DNA region will provide different Tm.

A robbery and crime property case at a farm was investigated using real-time PCR combined with HRM analysis. After burning two yards of a wheat field, the suspects stole several tons of a brand new variety of wheat, transported it in a truck, then distributed it among people living in a nearby community. The truck was found by the police and wheat grains were collected from the vehicle.

Genetic analysis of wheat grains collected from the truck (evidence) was performed, and the results were compared to those obtained from wheat plants collected at the farm (crime scene). Control wheat grains were also included in the analysis. Briefly, wheat DNA was extracted from the grains using the Plant DNAzol® kit by Invitrogen™ and quantified with a fluorometer Qubit® 2.0 by Invitrogen™. HRM analysis using ITS 2-3 primers was performed in an Illumina's® Eco real-time PCR system. HRM analysis showed indistinguishable melting curves for wheat grains collected in the truck (evidence) and grains collected at the farm (crime scene).

The HRM strategy enabled the "molecular traceability" of the wheat grains to the crime scene, demonstrating the usefulness of this approach for the identification of closely related species and its application as a potential forensic molecular tool. Two suspects were arrested and prosecuted.

Forensic Botany, DNA Typing *Triticum Aestivum* **L, DNA Barcoding**

B60 Using DNA Barcoding to Detect Fish Substitutions in Brazil

Carlos B. Carvalho, PhD, Sqs 212 Bloco K Apt 207, Brasilia, Distrito Federal 70275110, BRAZIL*

After attending this presentation, attendees will understand DNA barcoding and the use of this technique in Brazil by a forensic laboratory to detect fish substitutions.

This presentation will impact the forensic science community by reinforcing the utility of DNA barcoding in forensic casework, including food fraud investigations.

Fish substitutions are usually a fraudulent way of making a product more profitable by swapping high-value species for lower-value ones. Besides being a form of economic deception, this illegal practice may cause health problems or damage the environment. The inadvertent consumption of some species that have the potential to cause allergic reactions, contain toxins and contaminants, or other species that are currently overexploited or protected, are some of the consequences of this illegal practice. Since processed fish products usually lack the external morphological characteristics used for species recognition, fraudulent substitutions are very common.

When morphological identification is compromised, genetic identification can be used to associate unknown samples to a reference sample by comparing sequences of mitochondrial genes. DNA barcoding is a universal system for cataloging and identifying species based on approximately 650 base pair sequences of the Cytochrome c Oxidase (COI) mitochondrial gene. Created as part of this system, there is an international publicly available reference database Barcode Of Life Data Systems (BOLD), with authenticated sequences and a search engine used for species identification. DNA barcoding has been used successfully to identify fish substitutions in many countries in the past few years.

In this study, the Brazilian Federal Police DNA Laboratory used DNA barcoding to identify 93 fish fillet samples collected from ten seafood processing plants in 2013 and 2014. The large majority (81%) of the samples were mislabeled. Among the substitutions, the laboratory found the exotic cheaper species of flatfish *Atheresthes stomias* and *Limanda aspera* sold as the Brazilian coast genus *Paralichthys*, the Alaska pollock *Gadus chalcogrammus* being passed off for the Argentine hake *Merluccius hubbsi*, and the protected Wreckfish *Polyprion americanus* labeled as a grouper species. Several other cases of substitutions involving species commonly traded in Brazilian markets are also discussed. Because of these identifications, some processing industries in the southern region of Brazil were put under special supervision by the Brazilian food safety authorities. This study represents a pioneer use of DNA barcoding in food fraud investigations by a police laboratory in Brazil and the results obtained reinforce the utility of this technique in forensic casework.

DNA Barcoding, Fish Substitutions, Food Fraud

B61 Effects of Bacterial DNA on Human Profiles

Kevin G. Smolar, MS, 1950 N Talbott Street, Apt 4, Indianapolis, IN 46202; Gina Dembinski, MS, Indianapolis, IN; and Christine J. Picard, PhD, 723 W Michigan Street, SL 306, Indianapolis, IN 46202*

After attending this presentation, attendees will understand the effects of bacterial DNA contamination on a human DNA profile, which not only affects quantitation results of the human sample but also produces artifacts that can be present in the resulting profile specific to the bacterial species tested.

This presentation will impact the forensic science community by demonstrating that bacterial contamination affects the sample quality and therefore the development and interpretation of a human DNA profile. For quantitation procedures, if there is a large presence of bacteria, they may skew the results of the human DNA present and can affect the quality of the development of the DNA profile. Furthermore, the presence of extraneous DNA on human DNA profiles often results in a reduced number of loci amplified, which in turn would affect interpretations and lower the statistical power of discrimination. As most kits are developed to be human specific, these results indicate that caution should still be used in interpreting the human DNA profile, especially in cases of decomposition in which there would be higher levels of bacterial contamination.

Most biological evidence obtained from crimes scenes is found in non-sterile environments, and therefore there is an opportunity for the forensic samples to become contaminated with environmental DNA. In particular, the effects of bacterial species that may contaminate forensic samples have not been extensively studied. This type of information could be especially important in cases where decomposition has occurred and bacteria are in abundance. The environmental effects on DNA samples via contamination from bacterial sources were examined by intentionally spiking human DNA samples with known concentrations of DNA from 16 common bacteria species associated with humans using the Quantifiler® Human DNA quantitation kit and the PowerPlex®16 HS system. Single species of bacterial DNA were added in varying quantities (1ng, 50ng, and 100ng) to a standard 1ng human DNA sample. Results indicate that as increasing amounts of bacterial DNA were added to quantitation reactions, the apparent amount of human DNA decreased, due to possible polymerase competition. During genotyping, *Bacillus subtilis* produced an artifact peak at the Thyroid Peroxidase (TPOX) gene locus near or at the "5" allele, even when only 1ng of bacterial DNA was present in the sample, and the same artifact was also still amplified when the bacterial DNA was tested alone, without human DNA present. With other bacterial species, there was severe allele and locus dropout, especially at D18S51, D16S539, and CSF1PO.

Bacteria, Decomposition, PowerPlex®16 HS

B62 Optimal Time for Forensic Screening of Evidence Based on Fluorescent Variation of Seminal Fluid

Jack N. Lane, MS, Bode Technology, 10430 Furnace Road, Ste 107, Lorton, VA 22079; and Donia Slack, MS, 10430 Furnace Road, Ste 107, Lorton, VA 22079*

After attending this presentation, attendees will understand the impact that both time and temperature have on human seminal fluid. Attendees will learn of the optimal detection window of time for seminal fluid based on the fluorescent trends observed.

This presentation will impact the forensic science community by providing an understanding of the natural variation of the fluorescent properties of seminal fluid as exposure time to the environment increases. Understanding the degree of variation in seminal fluid fluorescence over time may help investigators approach an investigation site or assist in the analysis of collected material. Providing investigators with a confident approach to seminal fluid detection will increase detection events while also assisting in scenarios in which no seminal fluid fluorescence is detected. The additional information gained from items processed using a detailed understanding of seminal fluorescence may aid in the conviction or exoneration of individuals associated with evidentiary items in which the presence or absence of seminal fluid served as a pivotal point of an investigation. The fluorescent trends observed may also help explain variation in findings of multiple laboratories or assist re-investigations as evidence may have aged following the collection or detection of the event in question.

During any collection scenario, detection of biological fluids such as seminal fluid on evidence is critical to its recovery. In the case of semen, detection is often dependent on analyst's ability to visualize the fluorescence that occurs naturally when seminal fluid is subjected to light in the wavelengths ranging from approximately 365nm to 480nm and visualized with an appropriate filter. Although it is well understood that seminal fluid can be viewed using an alternate light source due to the natural fluorescence of riboflavin and its cofactors flavin mononucleotide and flavin adenine dinucleotide, the degree to which human seminal fluid fluorescence may increase or decrease over time is not well documented. The present study explored the relationship of semen fluorescence over time to determine if an optimal detection window exists as well as the variability in semen fluorescence. To determine this detection window and assess the variability, multiple replicates of semen were collected from three donors and deposited into a 96-well optical plate. Samples were either left at room temperature 20°C-24°C or placed in a heated environment at 32°C. The samples were then excited at 365nm and emission was detected, in relative fluorescent values, at 465nm at multiple time intervals ranging from time 0hrs to 312hrs over the course of three weeks. Excitation and emission detection was performed using a standard 96-well fluorescent microplate reader, accessible to any forensic laboratory.

Results indicate that seminal fluid at time zero exhibits less fluorescence than aged or even heated seminal fluid. A statistically significant difference was observed for each of the three donors used when comparing the initial spotting values of seminal fluid and each of the succeeding time points. Temperature was also found to increase the rate at which fluorescent values increase; a statistically significant difference was observed between samples subjected to 32°C incubation and those incubated at room temperature, 20°C-24°C. Samples subjected to elevated temperatures produced higher fluorescent values than comparable samples held at room temperature. These results indicate that in high-profile cases in which detection of semen is critical to evidence collection, it may be preferable to allow an item of evidence to age at elevated temperatures, or even room temperature, before an analyst commences a forensic screening for semen using alternate light sources.

Semen, Alternate Light Sources, Seminal Fluid Fluorescence

B63 The Identification and Analysis of Burnt Bloodstains

Rebecca Nelson, BS, Eastern Washington University, Dept of Chemistry & Biochemistry, 226 Science Bldg, Cheney, WA 99004-2440; Maranda M. Hirst, 1707 E Liberty, Spokane, WA 99207; and Peter Bilous, PhD, Eastern Washington University, Chemistry & Biochemistry, 226 Science Bldg, Cheney, WA 99004-2440*

After attending this presentation, attendees will learn: (1) which color-based blood screening test is the most effective for the identification of bloodstains exposed to high temperatures; and, (2) which bloodstains are likely to yield informative DNA profiles.

This presentation will impact the forensic science community by improving the overall efficiency with which crime scene investigators and forensic scientists analyze bloodstains from crime scenes that have deliberately been set on fire by criminals in an attempt to destroy evidence.

Various color-based and light-emitting blood screening tests are used to locate and tentatively identify the presence of blood at crime scenes. Typically, only those stains which yield a positive result are collected for subsequent DNA analysis; however, when criminals attempt to destroy evidence using deliberately set fires, for example an arson-homicide case, blood screening tests may not be effective and potentially useful stains may be missed. Furthermore, high temperatures cause significant DNA degradation, thus affecting the quality of the resulting DNA profiles.

In this study, three color-based blood screening tests were compared for their ability to identify bloodstains that were exposed to a range of temperatures that may occur in a structural fire. Polymerase Chain Reaction/ Short Tandem Repeat (PCR/ STR) analysis was conducted using the AmpFℓSTR® Profiler Plus® DNA typing kit to determine the impact of heat exposure on the resulting DNA profiles.

The three color-based blood screening reagents used were O-Tolidine (OT), phenolphthalein (KM), and the tetramethylbenzidine-based Hemastix® test strip. To determine the limits of detection of each reagent, bloodstain smears were made on glass and tile surfaces using neat, 1:10, 1:100, or 1:1,000 dilutions of non-human blood. Bloodstains destined for DNA analysis were made on glass using a mixture of non-human blood and human buccal cells. Samples were exposed to temperatures ranging from 60°C to 630°C for 5, 10, or 15 minutes.

All three reagents worked equally well with bloodstains prepared from neat and 1:10 dilutions of blood for all of the test conditions except those which were in direct contact with the alcohol-based flame. Only OT gave positive results with the latter samples. With respect to latent bloodstains prepared from 1:100 and 1:1,000 dilutions of blood, Hemastix® outperformed both OT and KM reagents. None of the reagents gave positive results with latent bloodstains which were in direct contact with the flame.

Not surprisingly, time and temperature were critical factors affecting the degree of DNA degradation and the quality of the resulting DNA profiles. Samples located 15cm above the flame (~160°C) generated complete DNA profiles with all of the exposure times tested. Samples located 10cm above the flame (~250°C) generated full DNA profiles but only for the five-minute exposure time. No profiles were obtained with the 10- and 15-minute exposure times. For samples located 5cm above the flame (~380°C), only those stains exposed for five minutes generated DNA profiles, and only partial genetic information was obtained. Stains which were in direct contact with the flame (~630°C) for five minutes generated extremely limited genetic information.

In summary, the identification of blood is possible in cases where an incendiary fire was used to destroy bloodstain evidence. The three reagents were equally effective for the analysis of visible bloodstains; however, only OT was effective with stains which were in direct contact with the flame. Hemastix® was the best reagent to use with latent bloodstains. These results showed that useful DNA profiles can be obtained from most of the tested bloodstains. The quality of the DNA results depended on the temperature and duration of heat exposure.

Burnt Bloodstains, O-Tolidine, Hemastix®

B64 Migration of Seminal Fluid Components and Spermatozoa in Semen Stains Exposed to Moisture

Lyndsey T. Brown, BS, 135 Northbridge Drive, Mooresville, NC 28115; Robin W. Cotton, PhD, Boston University School of Medicine, Biomedical Forensic Sciences, 72 E Concord Street, R 806, Boston, MA 02118; and Amy N. Brodeur, MFS, Boston University School of Medicine, Biomedical Forensic Sciences, 72 E Concord Street, R806, Boston, MA 02118*

The goal of this presentation is to provide attendees with a general understanding of the observed migration patterns of seminal fluid components and spermatozoa when semen stains are exposed to varying amounts of water and allowed to dry while positioned at different angles.

This presentation will impact the forensic science community by suggesting modifications for processing sexual assault evidence that has been exposed to moisture in order to maximize the likelihood of detecting semen and spermatozoa.

Typically, semen testing involves presumptive and confirmatory tests to determine the region in which a semen stain has been deposited prior to initiating DNA analysis; however, previous research has shown that the soluble components of seminal fluid, but not spermatozoa, migrated from their original location on cotton cloth upon exposure to porcine decomposition fluids and rainfall/dew.[1] This indicates that preliminary testing and detection techniques may result in areas being sampled that will not yield a successful DNA profile. It is hypothesized that the more moisture a semen stain is exposed to, the greater distance the soluble seminal fluid components will travel, but that minimal spermatozoa migration will occur. It is also reasoned that the extent and direction of semen migration will be dependent on the degree of wetness and the position (angle) of the substrate at the time of moisture deposition.

Neat semen was deposited onto swatches from cotton sheets and allowed to dry before being sprayed with 2mL, 5mL, or 10mL of water. The swatches were allowed to dry while lying flat, at 45°, or at 90°. A total of 13 swatches were created: one at each moisture level at each angle and one control with no water applied. The swatches were viewed with an Alternate Light Source (ALS) at 450nm using orange barrier filter goggles and photographed. Three swatches were sprayed directly with Acid Phosphatase (AP) Spot reagent to determine any potential interference with subsequent P30 and DNA analysis as well as to help determine distances for sampling. Three-millimeter punches were taken from each swatch at 13 locations (one from the center of the stain and four at 1cm, 4cm, and 7cm out from the perimeter of the stain in multiple directions), and were extracted for two hours prior to testing for the presence of P30.

Observation of the swatches under ALS revealed that the fluorescing component(s) of semen traveled up to 3cm from the original stain location. Less migration of fluorescence was observed with the samples exposed to 2mL of water compared to the samples exposed to 5mL and 10mL, regardless of the angle. The samples exposed to moisture while positioned at an angle showed fluorescence migration primarily to the sides and below the stain as expected due to gravity. This effect was more pronounced in the samples at 90° compared to those at 45°.

AP testing showed positive results beyond the original stain region, demonstrating seminal fluid migration for several centimeters in all directions. Positive P30 results were obtained for all swatches at 1cm from the stain in at least one direction. The sample exposed to 10mL of water at 90° also displayed a positive P30 result at 4cm from the stain.

Microscopic examination of slides made from the extracts of each cotton punch revealed minimal spermatozoa migration for all swatches; the majority of the samples outside of the stain deposition area showed no spermatozoa, although a few showed a single sperm cell. These findings demonstrate that the soluble components of semen stains that often aid in detection will migrate when exposed to moisture, while sperm cells containing genetic material largely remain in their original location. Results of DNA testing on select areas from each swatch at varying distances will be presented.

Semen Detection, Sperm, Moisture

B65 "Who Is My Father?" The Role of Forensic Genetics in The Resolution of a Paternity Case

Ciro Di Nunzio, MFS, PhD, Magna Graecia University, Viale Europa, Germaneto, Legal Medicine, Catanzaro 88100, ITALY; Isabella Aquila, MD*, Viale Europa, località Germaneto, Policlinico Universitario, S Venuta-Medicina Legale, Catanzaro 88100, ITALY; Michele Di Nunzio, BS, Università Magna Graecia, Viale Europa, Località Germaneto, Catanzaro, ITALY; Matteo Borrini, PhD, Liverpool John Moores University, RCEAP-School of Natural Science & Psych, Byrom Street, Liverpool L3 3AF, UNITED KINGDOM; Maurizio Saliva, MD, Via Carlo Maria Rosini 51, Pozzuoli 80078, ITALY; Flavio Saia, BS, Università Magna Graecia, Viale Europa, Località Germaneto, Catanzaro 88100, ITALY; and Pietrantonio Ricci, Viale Europa-Località Germaneto, Catanzaro, ITALY*

After attending this presentation, attendees will understand the problems associated with the identification of skeletal remains in southern Italian cemeteries in controversial parental relationship cases. The collaboration of experts in forensic pathology, anthropology, and genetics can greatly speed up the process of identifying the skeletal remains used in these cases.

This presentation will impact the forensic science community by suggesting a schematic approach in controversial parental relationship cases based on mixed skeletal remains.

In the Italian legal system, decedents must be buried in sealed wooden coffins and may be exhumed after a period of five to ten years. Each body is wrapped in a single sheet, inside of which is placed a document with brief details necessary for quick identification in the event of subsequent inspections. The number of bodies found in a tomb and information about the date of birth and death of each of these bodies are listed in the cemetery register.

A case of forensic judicial paternity is presented. An inquiry was made by a 64-year-old man (DG) against an alleged father (SLx). DG wanted to know who his biological father was. Unfortunately, DG learned that the alleged father had died. SLx was 72 years old at death, and his remains were placed in the family tomb with the remains of four other members of the family: the father (SP) (87 years old at time of death), the mother (88 years old at time of death), and two brothers (SF1-2) . At first, the judge had authorized the comparison of profiles between the presumed father (SLx) and the requesting party (DG); however, a preliminary inspection of the family tomb showed that cemetery personnel had not put the document with the critical information within each sheet. The document was placed only in the sheet that wrapped the remains of one the brothers of SLx. Therefore, the judicial authorities ordered a new investigation in order to establish through morphological and anthropometric assessments the identity of the skeletal remains in the tomb. Genetic testing was conducted on all human remains in order to obtain genetic profiles to be compared with the genetic profiles obtained from DG and his son (DGS). The forensic approach used was the one used to identify bodies following a mass disaster. At first, a consultation between the geneticist and the relatives of the decedents occured. This consultation provided very important information.

After a generic identification based on morphological and morphometric data, a radiological investigation was performed. Genetic analysis was conducted by comparing the genetic profiles obtained from the fragments of the femurs of SLx, SP, and SF with the profiles of DG and DGS. Genetic analysis showed the parental relationship between SP, SF, DG, and DGS, but no relationship was found with SLx with the remains that were assumed to belong to the alleged father. Therefore, the genetic puzzle was solved indirectly by comparing the genetic profiles of the relatives of the alleged father. The same genetic testing showed that during the displacement of the bones in the family tomb, the actual remains of SLx were lost and replaced with the remains of an unrelated individual. Moreover, DG learned that he was the grandson of SP and thus became aware of his origins and biological family despite the genetic investigation proving that the remains of the alleged father didn't exist and that SLx was unknown. This case of alleged paternity opened another court case about the true identity of the remains of SLx.

The multidisciplinary approach allows, in cases of doubt, for the identification of commingled human remains through the use of the same method used for mass disasters. The close collaboration between different disciplines such as forensic pathology, forensic anthropology, forensic radiology, and genetic forensic experts confirmed that these areas should always be used in paternity puzzles, especially when it comes to comparisons with buried human remains. The anthropological, radiological, and osteological evaluations can help in the identification and attribution of associated macroscopic remnants, while the genetic analysis, through the enhancement of the sampled subjects for molecular comparisons, can confirm the hypothesis of the investigators.

Forensic Science, Human Identification, DNA Paternity Testing

B66 Human Remains in Southern Italian Cemeteries: When the Type of Burial Influences the Results of DNA Extraction

Ciro Di Nunzio, MFS, PhD, Magna Graecia University, Viale Europa, Germaneto, Legal Medicine, Catanzaro 88100, ITALY; Isabella Aquila, MD*, Viale Europa, località Germaneto, Policlinico Universitario, S Venuta-Medicina Legale, Catanzaro 88100, ITALY; Maurizio Saliva, MD, Via Carlo Maria Rosini 51, Pozzuoli 80078, ITALY; Michele Di Nunzio, BS, Università Magna Graecia, Viale Europa, Località Germaneto, Catanzaro, ITALY; Francesco P. Busardo, MD, Viale Regina Elena 336, Rome, ITALY; Vittorio Fineschi, MD, PhD, University of Foggia, Forensic Pathology Dept, Ospedale Colonnello D'Avanzo, Foggia I-71100, ITALY; and Pietrantonio Ricci, Viale Europa-Località Germaneto, Catanzaro, ITALY*

After attending this presentation, attendees will better understand how the type of burial influences DNA extraction.

This presentation will impact the forensic science community by demonstrating the importance of the treatment of remains in southern Italian cemeteries and how this may promote the preservation of human bones and the success of DNA analysis.

Death causes the definitive transition from one social status to another. Understanding the nature of bodies and their status after death helps us appreciate this transition, which is encountered every time someone dies. Burial rituals are among the few visible forms of practice that may hint at beliefs about an afterlife. The practices, which include social, physical, body treatment, grave location, and cemetery organization, are determined by a complex mix of factors.

In the Sud Italian popular culture, prior to burial the deceased is in a transitional stage between life and death. After the 18th century, a double burial procedure was performed in order to verify this successful transition. In the first step, according to Presidential Decree 285/90, cemetery staff buried the corpse in a sealed wooden coffin. In the second step, after a period of five to ten years, the same staff exhumed the corpse. Family members washed and disinfected the remains, then wrapped them in a bed sheet and buried them in a stone niche for their final resting place.

Analyzed human remains were made available by judicial authorities for genetic identification or parental testing. The remains were in several decomposition stages due to different exposures to biotic and abiotic factors. The remains were collected from: (1) fire crime scenes where people killed by gun shots were burned to destroy evidence; (2) open spaces such as forests where missing people were found after a focused search; and, (3) cemetery areas were the remains were buried.

A correct analytical process is essential in order to perform DNA extraction from recovered human remains. Although DNA extraction can be carried out on any body part, compact femur bone represents the most suitable tissue, especially when DNA is degraded due to postmortem degenerative phenomena. The effects of decomposition on quality and concentration of DNA extracted from these mortal remains as well as the quality of obtained electropherograms were reviewed retrospectively on 100 femur fragments analyzed during the period of 2001 to 2014. The quality and quantity of extracted DNA, understandably, were often low, but the Short Tandem Repeat (STR) genetic profiles were acceptable for forensic purposes. In relation to the decomposition stage, the analyzed remains were grouped into four distinct stages: (1) fresh; (2) bloat; (3) decayed skeleton; or, (4) mummified.

The goal of the study was to observe that the treatment of the Sud Italian cemetery remains may promote the preservation of human bones and the success of the DNA analysis. The persistence of good bone condition in the burial environment is unusual as is the persistence of biomolecules in bone, but mummification is a common phenomena in South Italy cemeteries, where remains are buried in wooden coffins only for a limited time. After the disinterment, remains are co-located in stone niches. This procedure tends to protect bone as it appears much less deteriorated with respect to that collected from graves in which bodies are in contact with the ground.

Forensic Science, Human Identification, DNA Testing

B67 Development of a Portable Detection and Image-Processing System for Latent Fingerprints Using Time-Resolved Spectroscopy

Hidetoshi Kakuda, National Research Institute of Police Science, Physics Section, 6-3-1 Kashiwanoha, Kashiwa, Chiba 277-0882, JAPAN; Norimitsu Akiba, PhD, National Research Institute of Police Science, 6-3-1 Kashiwanoha, Kashiwa, Chiba 277-0882, JAPAN; Daisuke Imoto, MS, National Res Institute of Police Science, 6-3-1 Kashiwanoha, Kashiwa , JAPAN; Ken'ichi Tsuchiya, PhD, 6-3-1 Kashiwanoha, Kashiwa, Chiba 277-0882, JAPAN; Kenji Kurosawa, 6-3-1 Kashiwanoha, Kashiwa, Chiba 277-0882, JAPAN; Kenro Kuroki, PhD, 6-3-1 Kashiwanoha, Kashiwa, JAPAN; Shigeki Takeuchi, PhD, 2-1-1, Yabutaminami, Gifu-city 500-8974, JAPAN; and Osamu Shimoda, BS, 5-4-1, Yamatedouri, Tyuuou-ku, Hyogo Prefecture Police Headqrtrs, Kobe-city 650-8510, JAPAN*

After attending this presentation, attendees will understand how a portable detection and image-processing system for latent fingerprints using time-resolved spectroscopy is developed and applied to a preprocessed fingerprint.

This presentation will impact the forensic science community by presenting a report of a first attempt to develop a portable detection and image-processing system for latent fingerprints using time-resolved spectroscopy. It is expected that this system can be used for on-site detection and investigation of latent fingerprints.

Detection of fluorescence from latent fingerprints using time-resolved spectroscopy is one of the effective methods for visualizing latent fingerprints.[1,2] When a latent fingerprint is excited by irradiating with light, it emits fluorescence with a certain lifetime. This fluorescence provides information on the shape and components of the latent fingerprint. Since the light interacts with substances in a non-contact manner, an excitation of latent fingerprints by a light with modest power neither contaminates nor destroys the material evidence.

Although not only latent fingerprints but also background substances will emit fluorescence, it is possible to detect the fluorescence from latent fingerprints exclusively by using time-resolved spectroscopy. Time-resolved spectroscopy enables a detection of the light of interest by making use of differences in fluorescence lifetimes, which depend on substances. This spectroscopy is conducted by using a pulsed light source and a Charge-Coupled Device (CCD) camera with accurate temporal controls. After the image of the latent fingerprint is obtained, in some circumstances, it will be helpful to process it by a computer. Practically, since these devices include an optical system and tend to be large in size, the application of time-resolved spectroscopy to latent fingerprints has been limited to laboratory use.

This presentation reports on the development of a portable detection and image processing system for latent fingerprints using time-resolved spectroscopy in order to conduct on-site detection and investigation of latent fingerprints. It is noted that applying this system requires a preprocessing of a latent fingerprint for a fluorescence lifetime of several hundreds of µsec because the accuracy of temporal control of the programmable Matrox Iris GT, GT300C* CCD camera used in this system is limited to an order of µsec. This system adopts a Laser Diode (LD) wavelength 375nm as a light source and the programmable CCD camera equipped with a Central Processing Unit (CPU) for on-site data processing, such as image accumulations, to enhance Signal-to-Noise (S/N) ratio. Three timings concerning the LD and the CCD camera have to be provided: (1) light-emitting time of the LD; (2) delay time for opening a shutter of the CCD camera after the LD begins to emit; and, (3) exposure time of the CCD camera. Times (1) and (2) were set by a Sapphire Plus Pulse Generator, MODEL 9214+ delay pulse generator and time (3) was controlled by a program in the CCD camera. Both the pulse delay generator and the CCD camera were controlled and/or programmed by a tablet personal computer, which is connected to a portable monitor to enable on-site settings for instrumental conditions and checks of image processing results. One can also use a head-mount display instead of the monitor. These components are electrically supplied by lithium batteries. Constituents of the system weigh nearly 3kg in total and are portable.

This portable system was applied to a fingerprint preprocessed by Tris-Thienyl-Europium Chelate (T.TEC). The fluorescence lifetime of the T.TEC is approximately 500µsec. The light-emitting time of the LD was set to 400µsec and the exposure time of the CCD camera was adjusted to 200µsec. For the delay time for the CCD camera of 550µsec (i.e., the shutter of the CCD camera opens 150µsec after the LD emission ends), a fluorescence image of the latent fingerprint without the fluorescence from backgrounds was successfully obtained and clarified after 1,000 image accumulations and a histogram adjustment.

Portability, Latent Fingerprint, Time-Resolved Spectroscopy

B68 Fingerprint Ridge Drift: An Undescribed Phenomenon

Josep De Alcaraz-Fossoul, PhD, University of Barcelona, Carrer Casanova, 143, 3rd Fl, North Wing, Faculty of Medicine - Forensic Genetics Laboratory, Barcelona, Catalonia 08036, SPAIN; Carme Barrot, PhD, University of Barcelona, Carrer Casanova, 143, 3rd Fl, North Wing, Faculty of Medicine - Forensic Genetics Laboratory, Barcelona 08036, SPAIN; Luke McGarr, BSc, The Corner House Business Centre, 2, Albert Road, Ripley DE53FZ, UNITED KINGDOM; Karen Stow, MSc, The Corner House Business Centre, 2, Albert Road, Ripley DE53FZ, UNITED KINGDOM; Katherine A. Hogrebe, BS, 1581 Sherwood Village Circle, Placentia, CA 92870; and Manel Gené, PhD, University of Barcelona, Carrer Casanova, 143, 3rd Fl, North Wing, Faculty of Medicine - Forensic Genetics Laboratory, Barcelona 08036, SPAIN*

After attending this presentation, attendees will be informed about a newly discovered phenomenon named ridge drifting. Attendees will learn how to identify this feature that has never before been described.

This presentation will impact the forensic science community by introducing a new feature that describes changes in the topography of fingerprints that has previously gone unnoticed.

Fingerprint distortions have been described in the literature as being the result of applying a non-uniform pressure during deposition, combined with the inherent elasticity of friction ridge skin and the curved anatomy of the finger. In addition, fingerprint image deformations can also occur as a consequence of camera lens defects or are caused by the visualization/development process. These alterations of the fingerprint topography and of the acquired image are usually considered during a comparison process between a latent and an exemplar (inked or scanned) fingerprint.

The aforementioned distortions are characterized by: (1) being caused by an extrinsic force or action; (2) affecting entire areas of the deposition (or its image); and, (3) altering the overall flow of a series of contiguous ridges. In consequence, the ridges are "artificially" deformed, modifying the minutiae/ridge pattern and hindering comparisons. Unlike these identifiable types of deformations, a visual phenomenon that modifies the fingerprint at a ridge scale is described here and named "fingerprint ridge drift."

In an experiment to determine the degradation patterns of latent fingerprints, a sequence of impressions (eccrine and sebaceous) were deposited on non-porous surfaces (plastic and glass) by applying similar pressures for the same lengths of time. These were aged under three different light conditions (direct sunlight, shade, and darkness) for a period of six months, visualized with titanium dioxide over different time periods, and photographed. No further treatment or manipulation was performed on the samples. Photographs of fresh fingerprints were then compared with all of the aged prints. The analyses revealed that under certain environmental conditions, an individual ridge could randomly change its original position regardless of its unaltered adjacent ridges. This modification produced a change in the distribution of minutiae in the fingerprint at that specific location.

Currently, the causes of this phenomenon are not well understood. It is hypothesized that it could be the result of either: (1) a microscopic movement of the ridge over the non-porous surface by a diffusion (sliding) effect; or, (2) a process of degradation that affects only specific locations along the same ridge (selective degradation). In both cases, it would be a process exclusively associated with the intrinsic natural aging process of a latent fingerprint. At this time, the second option seems the most plausible. The study of superimposed fingerprint images has shown an apparent unchanged location of the affected ridges but a modification in their appearance.

It has been demonstrated that: (1) fingerprints from the same person can be slightly different if the factor "time" is included; (2) ridge drift occurs at random and has a very localized affect; (3) it is an intrinsic phenomenon not caused by external actions; and, (4) there is no obvious correlation between environmental conditions and ridge drift. To be confirmed, this discovery will help explain the detection of certain dissimilarities at the minutiae/ridge level between an aged latent fingerprint and its exemplar counterpart. Collaterally, the identification of this phenomenon will help determine more accurate "hits," identify potentially erroneous corresponding points, and rethink identification protocols, especially the common criteria of "no single minutiae discrepancy" for a positive match.

Fingerprint, Ridge, Aging

B69 Fingerprint Detection by Two-Photon Excitation With a Femtosecond Fiber Laser

Norimitsu Akiba, PhD, National Research Institute of Police Science, 6-3-1 Kashiwanoha, Kashiwa, Chiba 277-0882, JAPAN; Ryoya Takahashi, MS, JFE Techno-Res Corp, 1-Banchi, Kawasaki-cho, Chuo-ku, Chiba, JAPAN; Fumihiko Ichikawa, 1-banchi, Kawasaki-cho, chuo-ku, Chiba 260-0835, JAPAN; Akira Torao, 1-bncho, Kawasaki-cho, Chuo-ku, Chiba 260-0835, JAPAN; Naohiro Ishizawa, BS, Waseda University, 3-4-1 Okubo, Shinjuku-ku, JAPAN; Atsushi Nakamura, 3-4-1, Okubo, Shinjuku-ku, Tokyo, JAPAN; Takayuki Sota, 3-4-1, Okubo, Shinjuku-ku, Tokyo 169-8555, JAPAN; Hidetoshi Kakuda, National Research Institute of Police Science, Physics Section, 6-3-1 Kashiwanoha, Kashiwa, Chiba 277-0882, JAPAN; Daisuke Imoto, MS, National Res Institute of Police Science, 6-3-1 Kashiwanoha, Kashiwa, JAPAN; Ken'ichi Tsuchiya, PhD, 6-3-1 Kashiwanoha, Kashiwa, Chiba 2770882, JAPAN; Kenji Kurosawa, 6-3-1 Kashiwanoha, Kashiwa, Chiba 277-0882, JAPAN; and Kenro Kuroki, PhD, 6-3-1 Kashiwanoha, Kashiwa, JAPAN*

After attending this presentation, attendees will better understand a method of detecting fingerprints by two-photon excitation with an infrared femtosecond laser.

This presentation will impact the forensic science community by providing a non-contact, non-destructive, and non-invasive method to detect fingerprints. The proposed method does not affect DNA testing, which is one of the most important evidences in crime investigation.

Various methods such as using powder or chemical solutions are used for fingerprint detection. Conversely, methods using light such as laser and Light-Emitting Diode (LED) attract attention as a non-invasive method.[1] Fingerprint detection using fluorescence is an especially useful technique in forensic sciences. The visualization of latent fingerprints with an Ultraviolet (UV) -pulsed laser by time-resolved spectroscopy has been studied.[2] Even if the fluorescence of a background is strong, it is possible to visualize fingerprints by this time-resolved method using the difference of fluorescence lifetimes; however, it is a concern that fingerprints and deposits around them are damaged by UV light, which may affect other forensic examinations. It is important to use a less destructive method for criminal identification.

Therefore, this study focused on two-photon excitation with an infrared femtosecond laser. The visualization of latent fingerprints by two-photon excitation with a femtosecond solid-state laser is presented.[3] A compact system for on-site use is currently being constructed by replacing a large Ti:Sapphire solid-state laser to a small fiber laser, because mobility is required. In this study, fingerprint detection by two-photon excitation with a femtosecond fiber laser was performed in order to miniaturize the system.

Two-photon excitation was carried out with a femtosecond fiber laser and a fast-gated image Intensified Charge-Coupled Device (ICCD) camera. Repetition rates of the laser and ICCD camera were 50MHz and 500kHz, respectively. Pulses were picked with a frequency divider for the time-resolved spectroscopy. Damage to samples was reduced by scanning laser light with a galvano mirror and a resonant scanner. The objective lens was 20X (*N.A.*=0.4). Samples were placed on an X-Y-Z axis motorized stage. The excitation wavelength was 780nm and laser power was approximately 200mW to 300mW. Two-photon excitation at 780nm corresponds to one-photon excitation at 390nm. The irradiated area was approximately 50µm x 50µm.

At first, tests were performed using a green fluorescent pen. Gate width and exposure time were 10ns and 10s, respectively. A fluorescence spectrum whose peak of approximately 500nm was acquired. Since the peak of the emission spectrum was shorter than 780nm of excitation, it was confirmed that two-photon excitation occurred using this system with a fiber laser. Subsequently, the fluorescence spectrum of a fingerprint was measured. Gate width and exposure time were 2ns and 60s, respectively. A broad spectrum ranging from 400nm to 500nm was obtained, whose peak was approximately 450nm. It consists of the previous experiments using a femtosecond solid-state laser. Therefore, these results suggest that it was due to two-photon excitation of the fingerprint with the fiber laser. Furthermore, the lifetime of the inherent fingerprint was measured and found to be approximately 1.5ns. Finally, latent fingerprints on ceramics were visualized. Gate width and exposure time were 8ns and 20s, respectively. The ridge of a fingerprint was detected by two-photon excitation. In addition, fluorescence of a piece of skin was strongly detected. For future consideration, the researchers plan to visualize the fluorescence of additional fingerprints.

Fingerprint, Fluorescence, Two-Photon Excitation

B70 Method Validation Parameters for Drugs and Explosives in Ion Mobility Spectrometry (IMS)

A. Bakarr Kanu, PhD, Winston-Salem University, Rm 311, Dept of Chem, WB Atkinson, 601 S Martin Luther King Jr Way, Winston-Salem, NC 27110*

After attending this presentation, attendees will develop an understanding of practical analytical figures of merit that could be used to distinguish a false positive response from an actual drug of abuse or explosive using IMS. A false positive response is when an interfering compound produces a response identical to that of a target compound.

This presentation will impact the forensic science community by providing data that will be very useful in solving problems with false positive response when IMS is used in the field. This presentation will add to research already performed in forensic instrumental analysis by broadening understanding of analytical figures of merit that could help unravel how well a target compound can be discriminated or separated from a false positive response.

A major problem with field measurements is the possibility of false positives. False positive responses result in loss of time, and further testing may be required to insure that target explosives or drugs of forensic interest may be absent or present in a given circumstance.[1] In the complex forensic world, it is becoming increasingly important to develop accurate parameters to reliably identify forensic samples. Method validation is the process of proving that an analytical method is acceptable for its intended purpose. Developing method validation parameters for a specific forensic compound may be the answer to developing an accurate identification marker for substances like drugs and explosives of forensic interest.

Certified reference materials of drugs and explosives samples were prepared at different concentrations and analyzed with an Electrospray Ionization-High-Performance Ion Mobility Spectrometry (ESI-HPIMS) to determine method validation parameters for drugs and explosives. The preliminary results have determined the following method validation parameters for drugs of abuse and explosives: conditional reduced mobility, limit of detection, limit of quantification, control chart, linearity, sensitivity, accuracy precision, range, resolving power, and reporting limit.[2-6]

In conclusion, the preliminary data suggests that method validation parameters, when correctly implemented, could be used as a unique identifier for forensic samples. The result holds great promise for detecting and identifying forensic samples and reducing false positive rates.

Method Validation, Identity Confirmation, ESI-HPIMS

B71 Quantitation of Major Cannabinoids Found in Seized Marijuana Using Automated Headspace/ Solid-Phase Microextraction Coupled With Gas Chromatography/Mass Spectrometry (HS/ SPME-GC/MS)

Anastasia M. Brown, BS, 3207 Peddicoat Court, Woodstock, MD 21163; James D. Sweet, PhD, U.S. Customs and Border Protection, LSSD, 4150 Interwood S Parkway, Houston, TX 77032; and Jorn Chi-Chung Yu, PhD, Sam Houston State University, Dept of Forensic Science, Box 2525, Huntsville, TX 77341*

After attending this presentation, attendees will better understand using automated HS/SPME for the quantitation of Δ9-trahydrocannabinol, cannabidiol, and cannabinol from marijuana plant material.

This presentation will impact the forensic science community by providing an automated method for the quantitation of major cannabinoids through the direct headspace sampling of suspected marijuana samples. This presentation will enhance the applicability of HS/SPME-GC/MS to controlled substance analysis.

The term marijuana refers to the plant material of *Cannabis sativa* L. There are more than 60 natural cannabinoids found in marijuana. The primary psychoactive component is Δ9-Tetrahydrocannabinol (Δ9-THC). Other important components for forensic purposes in states with legalized marijuana include Cannabinol (CBN) and Cannabidiol (CBD). Current analytical methods for the detection of cannabinoids include solvent extractions followed by gas or liquid chromatography. Such methods have several limitations, including the use of hazardous solvents, the expense of said solvents, disposal of the waste generated from solvent use, and the time needed to perform such extractions. A solution that may eliminate such limitations is the use of an HS/SPME-GC/MS method to detect the cannabinoids found in marijuana samples.

In this research, an optimal automated HS/SPME-GC/MS method has been developed using cannabinoid standard reference materials and actual marijuana material samples. An internal standard of deuterated Δ9-THC (D3-Δ9-THC) and any standard reference samples used were placed in a vial and the solvent evaporated under a gentle air stream before analysis. The plant material was ground and sieved before being weighed out into sample vials. Unlike previous methods that would require the sample to be extracted with solvents before analysis, the HS/SPME-GC/MS method required the sample to be sealed in the sample vial and placed on a GC/MS autosampler that would carry out the HS/SPME extraction using a 23 gauge 100µm Poly(DiMethyl)Siloxane (PDMS) fiber and inject the extracted cannabinoids into the GC/MS. The optimized extraction temperature for cannabinoids was found to be 150°C for quantitative analysis, and the optimal extraction temperature was found to be five minutes. Regeneration of the PDMS fiber was achieved by heating the fiber to 250°C in the autosampler conditioning chamber during the run after the fiber was exposed to the inlet of the GC/MS.

Results from the optimized HS/SPME-GC/MS method show that quantitation of Δ9-THC, CBN, and CBD could be completed with an r^2 of 0.99 and combined accuracy of more than 95% when using an internal standard of D3-Δ9-THC. The quantitative ions used for Δ9-THC, CBN, and CBD were 310m/z, 295m/z, and 238m/z; 314m/z, 299m/z, and 231m/z; and 231m/z, 174m/z, and 121m/z, respectively. The same major cannabinoids can be seen with both traditional liquid extraction and HS/SPME methods; however, in some cases the HS/SPME-GC/MS method shows more cannabinoids than the liquid extraction. With a better sensitivity, faster sampling preparation, smaller sample quantity required, and cheaper supplies cost, HS/SPME-GC/MS quantitation can provide major advantages over traditional liquid extraction. Future research will include statistical analysis of the data collected from marijuana plant samples using an already optimized qualitative method and this quantitative method with the goal of being able to differentiate marijuana from different growers.

Marijuana, Quantitation, Solid-Phase Microextraction

B72 Analysis of Seized Hypodermic Syringes for Drug Content

Thomas A. Brettell, PhD, Cedar Crest College, 100 College Drive, Allentown, PA 18104; Robyn Pyle, MS, 777 W Germantown Pike, Apt 732, Plymouth Meeting, PA 19462; and Linda Burdick, BS, Bucks County Crime Laboratory, 850 Eagle Boulevard, Warminster, PA 18974*

After attending this presentation, attendees will have a better understanding of the results of analysis for controlled substances of 469 syringes seized by law enforcement and submitted to the Bucks County Crime Laboratory.

This presentation will impact the forensic science community by providing the results of one laboratory's experience of analyzing syringe residues for controlled substances by Gas Chromatography/Mass Spectrometry (GC/MS).

Drug paraphernalia is commonly submitted to forensic science laboratories for analysis of controlled substances. Paraphernalia seized by law enforcement often includes used syringes from drug abusers. The syringes are usually submitted to the laboratory with the needle intact. The proper submission of syringes should include a protective container labeled as a biohazard to protect anyone who must handle the evidence. Laboratories should have procedures in place to safely handle this type of evidence. It is a known fact that the sharing of syringes by intravenous drug abusers is a primary cause of the transmission of HIV and hepatitis B and C. Anyone who handles this type of evidence, particularly forensic chemists and law enforcement, is at risk of acquiring these diseases. For this reason, many laboratories choose not to analyze this type of evidence unless absolutely necessary.

However, there are a number of important reasons to analyze syringes submitted to crime laboratories. Laboratories may chose to have syringes analyzed because: (1) it is the only item in the case; (2) it may be the probable cause for arrest; (3) it may be essential for determining the cause of death in a death investigation; (4) possession of the contents of the syringe may be a significantly more serious offense than possession of other items in the case (e.g., a syringe with heroin vs. a bag of marijuana); or, (5) for other reasons specific to the case.

This presentation will report the results of analysis for controlled substances of 469 syringes seized by law enforcement and submitted to the Bucks County Crime Laboratory during the period of January 2014 through July 2015. The syringes were extracted with methanol. The methanol extract was evaporated, then reconstituted with five drops of methanol and divided into two vials, which were analyzed by GC/MS on separate instruments with different conditions. One-microliter injections of the methanol extracts were analyzed by GC/MS on an Agilent® 7890B gas chromatograph equipped with a 7693 autosampler interfaced to a 5977A mass selective detector. The column used was a 30m x 0.25mm x 0.25µm HP-5MS. The inlet temperature was 290ºC, the transfer line temperature was 250ºC, and the source temperature was 230ºC. One-microliter injections of the second aliquot were analyzed on a Perkin® Elmer® gas chromatograph model Clarus® 500 interfaced to a Clarus® 500S Perkin® Elmer® mass spectrometer. The column used was a 15m x 0.25mm x 0.25µm ELITE-5MS. Helium was used as the carrier gas for both columns with a flow of 1.0mL/min and linear gas velocity set at 38cm/sec. The inlet temperature was 290ºC, the transfer line temperature was 270ºC, and the source temperature was 250ºC. The mass scan range was set at 40m/z-500m/z for all samples. The column temperature program was optimized on both columns to ensure baseline resolution of heroin and 6-monoacetylmorphine (6-MAM). The initial column temperature was 130ºC with a hold time of 2.0 minutes, then the oven temperature was increased at 15ºC/min to 250ºC without a hold time and increased again at 15ºC/min to 320ºC with a final hold time of 3.0 minutes. The samples were run in split mode and with a 50:1 split ratio.

Of the 469 syringes analyzed, 71% were positive and 62% of the 294 cases analyzed were positive. The most common drug identified was heroin (46%). Other drugs identified were morphine (11%), cocaine (5%), methamphetamine (3%), fentanyl (1%), oxycodone (1%), and buprenorphine (1%) as well as various cutting agents, heroin metabolites and naturally occurring opiate alkaloids. Caffeine (16%) was the most common non-controlled substance detected.

Controlled Substances, Syringes, GC/MS

B73 The Development of a Novel Color Test for Improved Detection of Synthetic Cathinones

Charles R. Cornett, PhD, University of WI Platteville, Dept of Chemistry, Platteville, WI 53818; Nicole Kloepfer, University of Wisconsin-Platteville, 1 University Plaza, Platteville, WI 53818; Brooke Tashner, BS, University of Wisconsin-Platteville, Dept of Chemistry, 1 University Plaza, Platteville, WI 53818; and Tsunghsueh Wu, PhD, University of Wisconsin-Platteville, Dept of Chemistry, 1 University Plaza, Platteville, WI 53818*

After attending this presentation, attendees will better understand the development of a new color test for synthetic cathinones (aka "bath salts") and the scope of the test with respect to future derivatizations.

This presentation will impact the forensic science community by introducing a more reliable, presumptive means of detecting synthetic cathinones in the field and laboratory.

Color tests have been used by criminalists for decades to provide a rapid, inexpensive means of determining if an unknown compound merits further investigation. Law enforcement officers rely upon commercially produced presumptive color tests to determine probable cause for arrest and subsequent substance identification by crime laboratory personnel and techniques. Following a positive field presumptive test, the evidence (a potential controlled substance) is sent to the crime laboratory for further processing. This involves an indicative test and finally a confirmatory test. Color tests may also be used by crime laboratory personnel as a presumptive test.

Designer and emergent illicit drugs have entered the market at a rapid pace in the past five years, and synthetic cathinones (bath salts) are one example of these drugs. Synthetic cathinones are beta-keto phenethylamine derivatives that produce pharmacological effects similar to the Schedule I substances such as cathinone, methcathinone, and 3,4- Methylenedioxymethamphetamine (MDMA). The parent cathinone structure is easily derivatized at any of four sites to generate analogues not yet regulated by state legislation or the **Drug Enforcement Administration** (DEA) Scheduled substance list. Unfortunately, the derivatization of the cathinone structure has resulted in presumptive color tests that are often not detecting new bath salts, are providing different colors for different cathinone derivatives, or require several vials of various component reagents to be effective. It stands to reason that a reliable color test for synthetic cathinones capable of operating with great sensitivity over a wide range of environmental conditions and packaged in two or fewer ampules would constitute a significant advancement in the field.

This research and development has produced a two-stage color test utilizing proprietary reagents WuCo 1 and WuCo 2 in sequence. These reagents utilize organic dyes containing groups such as a sulfonic acid along with organic solvents and buffers described in this presentation. Experiments conducted demonstrate that the reagents are well suited for deployment and use in the field by law enforcement as well as the bench top as a presumptive test. The two-stage color test provides a consistent yellow color in the organic layer, and there are no impediments to its use in the field in a two-ampule system. In addition, the 20 synthetic cathinones tested can be detected in amounts ranging from microgram quantities to more than 30 milligram per testing package. Furthermore, the reagents produce effective results in a wide variety of environmental conditions, including at temperatures from -3°C to 40°C. This presentation details the 100% effectiveness in presumptive indication of a variety of synthetic cathinones.

Bath Salts, Synthetic Cathinone, Color Test

B74 Further Characterization of Opiates in Poppy Pod Tea Preparations

Angela S. Mohrhaus, BS, 6751 Steger Drive, Cincinnati, OH 45237; Heather A. McCauley, BS, 6751 Steger Drive, Cincinnati, OH 45237; Jill M. Robinson, MFS, 6751 Steger Drive, Cincinnati, OH 45237; and Samuel R. Gratz, PhD, 6751 Steger Drive, Cincinnati, OH 45237*

B75 Rapid Screening of Seized Drugs Using Direct Analysis in Real-Time Mass Spectrometry (DART®-MS)

Yuriy Uvaydov, MS, 99 Tenth Avenue, Ste 721, New York, NY 10011*

After attending this presentation, attendees will understand how DART®-MS can be applied for the screening and identification of commonly encountered drugs of abuse. Specifically, this presentation will demonstrate the advantages and limitations of DART®-MS over traditional instrumental techniques such as Gas Chromatography/Flame Ionization Detector (GC/FID), Gas Chromatography/Mass Spectrometry (GC/MS), and Liquid Chromatography/Mass Spectrometry (LC/MS).

This presentation will impact the forensic science community by explaining how DART®-MS can be effectively applied as a screening and identification technique for the presence of illicit drugs in single- and/or multi-unit submissions of evidence.

There are currently several existing instrumental techniques that can be applied for screening and identification of commonly encountered drugs of abuse. Typically, analysis of seized drug evidence consists of a series of presumptive and confirmatory tests. Traditional presumptive tests may include color, microcrystal, Thin-Layer Chromatography (TLC), GC, and/or Ultra High-Performance Liquid Chromatography (UHPLC). Confirmatory techniques, on the other hand, may include GC/MS, LC/MS, Fourier Transform Infrared/Attenuated Total Reflectance (FTIR/ATR), and/or Nuclear Magnetic Resonance (NMR). The continuing demand for faster, more efficient methodologies demonstrates the need to incorporate newer analytical instrumentation into the classical workflow.

DART®-MS is a relatively new ionization technique for mass spectral analysis of compounds. DART®-MS allows for ambient ionization of small molecules from different samples without sample preparation. The samples are directly introduced into the ion source using tweezers or capillary glass tubes and are desorbed from sample surface by flow of heated nitrogen or helium while being ionized. In conjunction with the High Resolution Accurate Mass Spectrometer (HRAMS), DART®-MS can deliver rapid results with accurate mass determinations and highly specific mass-to-charge spectral data.

The purpose of this work was to develop a method for rapid detection of drugs (target or unknown) utilizing HRAM coupled to a DART® ionization source. In this study, a 24-second screening method was developed for the detection of commonly encountered illicit drugs. Mass spectral acquisition of data was performed in positive mode utilizing a DART®-Simplified Voltage and Pressure (SVP) ion source with Thermo Fisher's Exactive Plus Mass Spectrometer. Powdered samples were introduced directly into the ion source via glass capillary tubes utilizing the Dip-It linear rail system that is connected to the DART®-SVP ion source. Data acquisition included fragmentation patterns utilizing Source-Induced Dissociation (SID), generated at 30eV, 60eV, and 100eV.

Preliminary results demonstrated successful identification of controlled substances in various drug mixtures. For example, unknown samples containing heroin, fentanyl, and dipyrone were correctly identified based on the characteristic peaks with the assigned chemical formulas. Similarly, unknown samples containing cocaine, levamisole, and phenacetin were also correctly identified. The results also showed that DART®-MS identifications of major sample components in other various drug mixtures were correctly identified. The identification of minor components presented a challenge and may require further optimization of the HRAM/DART®-MS acquisition parameters. Overall, this approach is expected to decrease analysis time, increase efficiency in screening multi-unit drug submissions of evidence, while maintaining cost-effectiveness and achieving valid reproducible data.

DART®-MS, Forensic Drugs, Rapid Screening

B76 Evaluation of a Direct Analysis Portable Mass Spectrometer (MS) for the Detection of Drugs and Related Substances

Nichole D. Bynum, MS, RTI International, 3040 Cornwallis Road, Bldg 3, Research Triangle Park, NC 27709; Katherine N. Moore, MS, 2526 Folsom Lane, Morrisville, NC 27560; Zachary E. B77 Analysis of Cannabis for the Presence of Pesticides and Adulterants With High Resolution Tandem Mass Spectrometry

Werner Bernhard, DSc, IRM University of Bern, Buehlstrasse 20, Bern CH-3012, SWITZERLAND; Stefan Koenig, PhD, Institute of Forensic Medicine, Buehlstrasse 20, Bern 3012, SWITZERLAND; Susanne Nussbaumer, PhD, Institute of Forensic Medicine, Buehlstrasse 20, Bern 3012, SWITZERLAND; and Wolfgang Weinmann, PhD, Institute of Forensic Medicine, Bühlstrasse 20, Bern 3012, SWITZERLAND*

After attending this presentation, attendees will be aware that pesticides are found in seized cannabis. These compounds are used in order to promote growth and prevent insects/fungi from destroying the plants or reducing the yield. Acquisition of mass spectra in Sequential Windowed Acquisition of All Theoretical Fragment Ion Mass Spectra (SWATH) mode on a quadrupole Time-Of-Flight (qTOF) instrument allows for unambiguous determination of the pesticides present in marijuana samples.

This presentation will impact the forensic science community by presenting a rapid and reliable analytical method to detect pesticides in marijuana that were used during the cultivation and were not degraded before harvesting.

Goals: Cannabis consumption is observed as a wide-spread phenomenon and in some cases the cannabis users also consume toxic contaminants without being aware of possible side effects and long-term adverse health effects. In order to assess the exposure of cannabis users to pesticides and adulterants (e.g., synthetic cannabinoids), a specific High-Performance Liquid Chromatography (HPLC) qTOF method was developed for herbal marijuana samples.

Methods: The sample collection was performed during the routine forensic analysis of seized drug materials. The plant samples were then processed via the Quick, Easy, Cheap, Effective, Rugged and Safe (QuEChERS) method and further cleaned by dispersive solid phase extraction. The prepared samples were injected onto a core shell column (Biphenyl, 50mm x 2.1mm, 2.6µm), analyzed on a qTOF instrument, and measured by non-targeted acquisition (SWATH). Typical run times of 20 minutes from injection to injection were achieved.

Results: A total of 151 marijuana samples from different locations within Switzerland were analyzed by this newly developed method. These samples were collected during the past 12 months and stored at room temperature in the laboratory. The scan parameters were optimized in order to meet the complexity of these plant samples. The following parameters were found to be most favorable for significant library hits: scan range from 50Da to 950Da, scan windows of 25Da, scan time of 35msec for each scan window,and collision energy of 35eV±15eV (collision energy spread). For unambiguous identification accurate mass of the precursor ions, Tandem Mass Spectrometry (MS/MS) spectra and retention time was used as criteria. These criteria were previously determined by injection of clean standard solutions of the pesticides into this system.

In 12 of these 151 samples, pesticides were found in various concentrations. Among these pesticides the following compounds were identified: propamocarb, imidacloprid, dimethoate, Diethyltoluamid (DEET), and metalaxyl.

Conclusions: A straightforward and reliable method of analysis was developed for the detection of pesticides in marijuana as is already established as standard procedure for food and drinking water. These pesticides can represent additional health hazards for marijuana smokers and therefore a quality control for legal marijuana is certainly needed.

Pesticides, Marijuana, HR Tandem Mass Spectrometry

B78 Differentiation of Seized Marijuana Samples Using Automated Headspace/Solid-Phase Microextraction Coupled to Gas Chromatograph/Mass Spectrometer/Flame Ionization Detector (HS/SPME-GC/MS/FID) and Principal Component Analysis (PCA)

Jessica Winborn, BS, 2405B FM 1375, E, Huntsville, TX 77340; James D. Sweet, PhD, U.S. Customs and Border Protection, LSSD, 4150 Interwood S Parkway, Houston, TX 77032; and Jorn Chi-Chung Yu, PhD, Sam Houston State University, Dept of Forensic Science, Box 2525, Huntsville, TX 77341*

After attending this presentation, attendees will better understand automated HS/SPME-GC/MS/FID methodology and its application to the differentiation of different marijuana samples.

This presentation will impact the forensic science community by providing an automated method for the differentiation of different marijuana seizures. This presentation will enhance the applicability of HS/SPME-GC/MS/FID to controlled substance analysis and allow agencies to gather intelligence about drug distribution networks.

The term marijuana refers to the plant material (mostly leaves and buds) of *Cannabis sativa* L. There are more than 60 natural cannabinoids found in marijuana. The primary psychoactive component is Δ9-Tetrahydrocannabinol (Δ9-THC). Marijuana is federally a Schedule I controlled substance, but on a state level it ranges from fully illegal to fully legal. The change in legislation has raised new concerns for law enforcement. One of these concerns is whether legally grown marijuana is being diverted out of states where it is legal for recreational use to ones in which it is illegal. The ability to track the flow of marijuana to and within different jurisdictions will be an important tool for law enforcement officials.

In this study, an HS/SPME-GC/MS/FID method has been applied to seized marijuana samples to analyze their cannabinoid profile in order to assess common origin between seizures. The plant material was ground and sieved before being weighed out into sample vials. The vials were placed on a GC/MS autosampler that would carry out the HS/SPME extraction using a Polydimethylsiloxane (PDMS), 23 gauge, 100µm absorbent fiber and the extracted sample was injected into the GC/MS. The extraction temperature for cannabinoids was 150°C and the optimal extraction time was five minutes. Regeneration of the PDMS fiber was achieved by heating the fiber to 250°C in the autosampler conditioning chamber during the run after the fiber was exposed to the inlet of the GC/MS. The resulting cannabinoid profiles for each seizure of marijuana were analyzed using Principal Component Analysis (PCA) to assess the differences between them.

Results from this study show the analysis of cannabinoid profiles using HS/SPME-GC/MS and PCA to have great potential for being able to differentiate different marijuana samples. One of the seizures used in this study was differentiated from the other two. The remaining two seizures showed overlap between them. Future research will include the analysis of other non-cannabinoids present in the chemical profile of marijuana samples to improve the discriminatory power of this method.

Marijuana, HS/SPME, Principal Component Analysis

B79 The Effects of Ultraviolet (UV) Radiation on Time-Dependent Changes in the Composition of Latent Fingerprints

Allyson K Digmann, BS, Southeast Missouri State University, Dept of Chemistry, 1 University Plaza, Cape Girardeau, MO 63701; and James W. McGill, PhD, Southeast Missouri State University, Dept of Chemistry, One University Plaza, Cape Girardeau, MO 63701*

After attending this presentation, attendees will understand how UV radiation affects the perceived age of latent fingerprints, with age referring to the time since the fingerprint was left on a surface.

This presentation will impact the forensic science community by providing fingerprint analysts with additional information to use when working a case. Previous research has been performed to determine the time since deposition of a fingerprint as well as the age of the fingerprint donor, but there are many environmental factors that have yet to be considered, with UV radiation being one of those factors. This information can be used to help investigators include or exclude fingerprints from a crime scene.

Fingerprint ridge patterns have been demonstrated to be unique to an individual for many years. While latent fingerprints found at a crime scene are useful in including or excluding an individual from being present at a crime scene, they currently provide little information without an exemplar fingerprint for comparison. Studies have been undertaken to determine if more information can be established from a latent print, such as characteristics of the person who left the fingerprints, as well as how long the fingerprint has been on that surface, also known as time since deposition. Current research suggests that the time since deposition can be determined under controlled laboratory conditions and also that the donor age can be determined to within five years for suspects more than 20 years old; however, there are many environmental elements that must also be considered for real-world application.

In this study, there are two variables: time since deposition and UV radiation levels. Ongoing research suggests that time-dependent changes in the fingerprint composition can be used to estimate the time since deposition in ambient laboratory conditions. For this study, UV radiation wavelengths were controlled to determine if UV radiation affects the time-dependent changes of the fingerprint composition. There were four time-since-deposition groups: one day, one week, one month, and four months. The ages used ranged from 18 years old to 24 years old. For this study, donor age was not a variable in order to achieve more specific results for the time since deposition. For each donor, 24 fingerprints were taken and divided into two trials of 12. Those 12 prints were further divided into the four time-since-deposition groups, with each group having three prints, one with no added radiation, one with added UVA radiation, and one with added UVB radiation. All prints were on the same surface: aluminum. The added radiation levels were controlled using UV lamps. This allowed for each print to only be exposed to the added radiation or not to be exposed to any radiation at all.

To determine if the UV radiation affected the time since deposition, the radiated fingerprints were compared with the non-radiated prints for the corresponding time-since-deposition group. After reaching the target time since deposition, the prints were tested using Fourier Transform Infrared Spectroscopy (FTIS) and Raman spectroscopy to determine the chemical composition of the fingerprint over time, followed by chemometric analysis to identify time-dependent changes in each fingerprint. These changes were then compared to ascertain the correlation between UV radiation and any changes in the time since deposition in the prints to which UV radiation was added.

Fingerprint, Time Since Deposition, Ultraviolet Radiation

B80 Effects of Donor Age and Water Exposure on the Quality of Oil Red O-Stained, Water-Exposed Latent Prints

Kitrina D. Skaggs, BA, Southeast Missouri State University, Dept of Chemistry, 1 University Plaza, Cape Girardeau, MO 63701; James W. McGill, PhD, Southeast Missouri State University, Dept of Chemistry, 1 University Plaza, Cape Girardeau, MO 63701; and Madalyn R. Robinson, BA, Southeast Missouri State University, Dept of Chemistry, 1 University Plaza, Cape Girardeau, MO 63701*

After attending this presentation, attendees will understand how the age of the fingerprint donor affects the quality of Oil Red O-stained latent prints that have been previously wet with water. Attendees will also understand how the quality of Oil Red O-stained latent prints that have been previously wet with water is affected by exposure to three common aqueous mixtures.

This presentation will impact the forensic science community by expanding the understanding of the applicability, scope, and limitations of Oil Red O lipid staining reagent for visualizing latent fingerprints on paper that has previously been wet with water. A better understanding of these variables — including donor age and exposure to different aqueous mixtures — will guide the user in application of this reagent in casework and validation studies.

Oil Red O is a soluble lipid stain that was reported in 2004 to be efficacious for partitioning into and staining sebaceous materials in latent fingerprints. It is considered particularly useful for visualizing latent fingerprints on porous surfaces that have been wet with water, such as wet currency or paper. While other water-soluble components such as salts and amino acids may be washed away by exposure to water, water-insoluble fatty components of the fingerprint residues are much more resistant to removal by water and often persist after exposure to water.

In seeking to better understand the utility, scope, and limitations of Oil Red O stain reagent in visualization of lipidic components of latent prints, the present study examines the effects of two variables on the quality of latent prints stained using Oil Red O: Variable 1 — exposure to moving water of three varieties (tap water, Mississippi River water, and water containing laundry detergent); and, Variable 2 — the age of the latent print donor (from 1 to more than 60 years old). These two variables are expected to affect the lipid composition of latent fingerprints in a number of ways.

Water is known to have a much smaller effect on sebaceous materials deposited on a surface than on inorganic constituents such as salts; however, different types of water might be expected to affect the lipid content more than pure water. For example, tap water contains ions, disinfectants, and disinfectant by-products that might interact physically or chemically with sebaceous materials to alter their makeup. River water contains sediment that might act as a physical abrasive, thereby mechanically removing sebaceous materials from a surface. Finally, laundry detergent is used as a surfactant to aid in removal of greasy stains and soils from fabrics in the presence of water. It would reasonably be expected to remove sebum from paper as well.

Donor age is well-established as a variable affecting the chemical composition of latent fingerprints. In fact, fingerprint donors have been classified and donor age predicted based on analysis of the chemical composition of the print residues. Children are known to have more, shorter chain, free fatty acid components in their fingerprints, leading to higher volatility and thus shorter persistence in abduction cases. Teenagers and young adults typically have oilier skin, characterized by longer chain lipids, fatty, waxy, and cholesteryl esters, which decrease in concentration into young adulthood and middle age. Finally, older adults are characterized by decreasing amounts of sebum and drier skin. Since Oil Red O partitions into lipid material, these changes should manifest in varying quality of stained fingerprints.

Fingerprint samples were collected on pieces of various papers, including typical office laser printer paper and cotton blend papers. Subjects deposited fingerprints in triplicate on various papers, which were then treated by exposure to moving water solutions using a mechanical agitator. The latent prints were then visualized using a prescribed staining procedure with Oil Red O dye solution. The stained prints were photographed and their quality was assessed using two methods: qualitative stain color intensity and visibility of a set of minutiae predetermined from examination of inked prints of the donor subjects. Effects of varying these parameters will be reported.

Oil Red O, Fingerprint Quality, Donor Age

B81 Fingerprint Loss in a Cancer Patient With No Side Effects

Luciano Garofano, PhD, Accademia Italiana di Scienze Forensi, Via G. D'Annunzio n.9, Parma 43100, ITALY; Francesca Negri, MD, PhD, Oncology Unit, University Hospital of Parma, University Hospital, Parma 43100, ITALY; Annamaria De Giorgi, MD, Oncology Unit, University Hospital of Parma, University Hospital, Parma 43100, ITALY; and Luigi Bisogno, Via N. Capuano, 10, Castel San Giorgio (Sa) 84083, ITALY*

After attending this presentation, attendees will better understand the effects of chemotherapy on fingerprints.

This presentation will impact the forensic science community by raising awareness of the effects of chemotherapy, which may cause the loss of papillary fingerprints.

The case of a 75-year-old man with stage III colon cancer who received a six-month adjuvant chemotherapy treatment with capecitabine and oxaliplatin with no side effects is presented. During the first six-month follow-up visit, he was healthy, but as he was leaving, he incidentally asked if chemotherapy could have altered his fingerprints. In fact, his bank had recently denied access because his fingerprints were not recognizable. Moreover, he had to switch off his iPhone® Touch ID because it would not work anymore.

As it was known that he had not experienced any grade of skin toxicity during chemotherapy, he was asked to be fingerprinted for comparison, but the older fingerprints were unavailable, which represented a big issue. After two months of unsuccessful research and attempting to find a solution, the patient reported that he was again able to enter his bank. By comparing his fingerprints during and after chemotherapy, the loss of fingerprints was confirmed due to the presence of thinner ridges, a narrowing of the height between the top and bottom of the groove, and the absence of the relief, thus creating problems in scanner readings.

Cases of fingerprint loss during chemotherapy have previously been reported and have always been associated with some degree of hand/foot syndrome; however, this particular situation is the first-ever reported case with no skin toxicity.

Two practical conclusions can be drawn from this information: (1) fingerprint alteration might also arise in the absence of other clinical signs and this can be a handicap in patients taking chemotherapy drugs; therefore, they should be aware of this possibility; and, (2) this process is reversible and therefore needs to be brought to the attention of banks and the police force in order to avoid unpleasant consequences.

Fingerprint, Chemotherapy, Loss

B82 Pyrolysis Products of BK-2C-B and BK-2C-I, Beta-Keto Analogs of 2,5-Dimethoxy-4-Bromophenethylamine

Pierce V. Kavanagh, PhD, Trinity College Dublin, College Green, Pharmacology & Therapeutics, Trinity Centre, SJH, Dublin, IRELAND; Kelly B. Texter, BS, University of Alabama-Birmingham, 15950 Meadow King Way, Milton, GA 30004-8814; Rachel Waymack, College of William and Mary, Ewell Hall, Williamsburg, VA 23187-8795; and Elizabeth A. Gardner, PhD, UAB Department of Justice, UBOB 210, 1530 3rd Avenue, S, Birmingham, AL 35294-4562*

The goal of this presentation is to develop a better understanding of the products that result from the pyrolysis of the ß-keto analogs of the 2,5-dimethoxyphenethylamines: (1) 2-amino-1-(4-bromo-2, 5-dimethoxyphenyl)ethan-1-one (ßk-2C-B); and, (2) 2-amino-1-(4-iodo-2, 5-dimethoxyphenyl)ethan-1-one (ßk-2C-I).

This presentation will impact the forensic science community by identifying the products produced during pyrolysis of the beta-keto analogs of the 2,5-dimethoxyphenethylamines and their potential toxicity. Detecting these products in biological samples may also aid toxicologists in the identification of the drug and the route of administration.

The family of psychedelic phenethylamines called "2Cs" were first synthesized in the 1970s by Alexander Shulgin and published in his book, *Phenethylamines i Have Known and Loved* (PiHKAL).[1] The chemical structure of the 2C compounds has methoxy groups at the 2 and 5 positions of a phenethylamine ring. The acronym of 2C refers to the two carbon atoms between the benzene ring and the amino group.

Although 4-bromo-2,5-dimethoxyphenethylamine (2C-B) was scheduled in 1995, the beta-keto analog did not appear as a legal high until 2013.[2,3] The only structural difference between 2C-B and *bk*-2C-B is the addition of the beta keto group at the carbon beta to the amino group. Even though 2-amino-1-(4-bromo-2,5-dimethoxyphenethyl)ethanone (*bk*-2C-B) was first synthesized in 1974, there is little scientific data available on its use as a recreational drug. The first literature report was a 2004 study of β-oxygenated analogs of 1-(4-Bromo-2,5-dimethoxyphenyl)-2-aminopropane.[4] Power et al. recently reported on the synthesis and *in vitro* metabolism of *bk*-2C-B and compared it to a purchased sample.[5] They also determined that *bk*-2C-B reacts in the injector port of the Gas Chromatography (GC) to form decomposition products, namely 1-(4-bromo-2,5-dimethoxyphenyl)-ethanone, and a dimer.[2] In this work, *bk*-2C-B was pyrolyzed in order to identify the substances inhaled when the drug is smoked.

For the pyrolysis reaction, a sample of *bk*-2C-B (5mg-9mg) was loaded into an aluminum foil boat, placed in the bottom of a 20ml crimp vial, and heated with a disposable lighter for approximately 30s until yellow vapors formed in the vial. The foil cup was removed and the flask was rinsed with acetonitrile to dissolve the residues for GC/MS. The derivication was an acetylation performed using 100 µL of acetic anhydride and heating at 70°C for three hours. The vial was cooled to room temperature and the contents analyzed by Gas Chromatography/Mass Spectrometry (GC/MS). For Trimethylsilyl (TMS) derivatization, the residue was taken up in N,O-Bis(trimethylsilyl)trifluoroacetamide (BSTFA) /toluene (1/1) and analyzed by GC/MS.

Twelve products were detected and confirmed by comparison to standards synthesized at Trinity College Dublin. They are primarily the result of bond cleavage and halogenation. Unlike cocaine and methamphetamine, most of the *bk*-2C-B decomposed during pyrolysis. The primary products from the pyrolysis of *bk*-2C-B are 1-(4-bromo-2-hydroxy-5-methoxyphenyl)-ethanone and 1-(4-bromo-2,5-dimethoxyphenyl)-ethanone. The Iodo analog were also detected after the pyrolysis of *bk*-2C-I. Four additional analogues to the *bk*-2C-B pyrolysis products and one distinct structure, 1-(2,5-dimethoxyphenyl)ethan-1-one) have been identified for *bk*-2C-I.

The pyrolysis of *bk*-2C-B produces chemicals that have been tested as fungicides and proton chromophores. The 1-(2,5-dimethoxyphenyl)ethan-1-one) is a skin, eye, and respiratory irritant, an ingredient in pesticides, and has been tested as a potential anti-cancer agent. Analysis is ongoing.

B83 Assessing the Utility of Detrital Quartz Surface Textures and Feldspar Mineral Chemistry for Forensic and Intelligence Applications

Jack Hietpas, PhD, FBI-ORISE, 2501 Investigation Parkway, Quantico, VA 22135; JenaMarie Baldaino, BS, 5012 Coachmans Carriage Terrace, Glen Allen, VA 23059; JoAnn Buscaglia, PhD, FBI Laboratory, CFSRU, 2501 Investigation Parkway, Quantico, VA 22135; Garrett McMahon, BS, ORISE-FBI, 2501 Investigation Parkway, Quantico, VA 22135; and Libby A. Stern, PhD, FBI Laboratory - CFSRU, 2501 Investigation Parkway, Quantico, VA 22135*

After attending this presentation, attendees will better understand the strengths and limitations of the light mineral fraction of soils as metrics for the characterization and discrimination of soil and dust samples.

This presentation will impact the forensic science community by demonstrating the techniques for the exploitation of quartz and feldspar as quantitative methods for the characterization of soil evidence, which may provide valuable prosecutorial evidence as well as lead identification for forensic investigations and intelligence purposes.

The mineral assemblages in soils are commonly utilized to make associations between people, objects, and locations. For forensic and provenance studies, the light mineral fraction (ρ<2.9g/cm3) of soils is not considered to be as discriminating as the heavy mineral fraction (ρ>2.9g/cm3); however, the light minerals typically account for 90%-99% of the fine-to-coarse (>50µm) mineral fraction and are, therefore, more likely to be present in sufficient quantity in the very small (<<1g) sample sizes commonly encountered in casework. The goal of this research was to investigate metrics to exploit potentially valuable information from the more abundant light mineral fraction of soils. To this end, 11 surface soil samples were collected from regions with distinct bedrock/surface geology, ecoregion, and physiography. This project investigated the two most common minerals in the light fraction of soils and sediments (quartz and feldspar). Interpretation of quartz surface textures using high-resolution Scanning Electron Microscopy (SEM) can be used to constrain environmental (littoral, subaqueous, eolian, among others) and petrogenetic (sedimentary, igneous, and metamorphic) origins.[1]

In addition, the major element composition of the detrital feldspar minerals was measured using quantitative SEM Silicon Drift Detector-Energy-Dispersive X-Ray Spectroscopy (SDD-EDS). The elemental composition of feldspar is highly variable and is closely related to the rock type from which it formed and thus may be used to infer the source rock type from which these minerals were derived.[2-5] Isolated grains were embedded in epoxy and subsequently ground and polished to expose the interior of the grains; quantitative analysis was performed using Desktop Spectrum Analyzer (DTSA-II), an open-source software package available from the National Institute of Standards and Technology (NIST).[6] Smithsonian Institution mineral and glass standards were used for calibration and as reference spectra for quantitative analysis.

Preliminary results show that the quartz surface textures (n=30-40 grains/sample) can be used to distinguish between several of the analyzed soil samples. In addition, the observed quartz surface textures correlate well with the geological and environmental settings from which the soils were collected. The elemental composition of isolated detrital feldspar grains (n=50-100 grains/sample) provided valuable information concerning the identity of the eroding local bedrock from which the soils were derived; however, several of the samples in this limited collection did not contain a sufficient number of feldspar grains for a meaningful, robust bedrock (source) assessment. The results from this research may provide new metrics and information for domestic criminal investigations and intelligence purposes.

Forensic Geology, Light Minerals, Provenance

B84 Chemical Pattern Recognition: What Can Be Extracted From Geo-Located Spectroscopic Data Sets?

Sergey Mamedov, PhD, 3880 Park Avenue, Edison, NJ 08820*

After attending this presentation, attendees will understand the usage of X-Ray Fluorescence (XRF) and Raman microscopy in applications of sand analysis, an important element in forensic identification of these materials.

This presentation will impact the forensic science community by serving as a key aspect of sand/soil analysis and as an example of a practical application of XRF and Raman spectroscopy to materials identification.

XRF and Raman spectroscopies are useful tools for analyzing substances and confirming their identity with little or no sample preparation. XRF provides information about the elemental composition of the material whereas Raman spectroscopy gives molecular information. Both techniques enable the recording of not only spectra of small sand particles (as small as 50-100 microns) but also hyper-spectral imaging and collection of average spectra over a given area. Multivariate Analysis (MVA) can produce chemical distributions of elements and/or material classification based on Principal Component Analysis (PCA) and Partial Least Square Discriminative Analysis (PLSDA) in particular with association between elements that can aid in the identification of bonded phases. The analysis of micro-XRF data and Raman data of sand taken from different areas can be used to identify geographic locations.

XRF and Raman analytical microscopes were used in this study. XRF spectra of the materials were collected using a 50keV acceleration voltage with an X-ray spot size of 1.2mm. Two excitation wavelengths (532nm and 633nm) were used to collect Raman spectra with a spot size of 10-100 microns, depending on the material. Samples of sand (10g in weight) were ground and the resulting powder was used for XRF and Raman measurements.

The spectra of sand from different locations (the United States, Europe, and the Middle East) were collected and analyzed by micro-XRF and Raman spectroscopy. XRF analysis was performed in the range of 1.00keV-40.96keV (<400 spectra). Because only few spectra have additional features in the energy range above 15keV, spectra were truncated and analysis was performed in the spectral range of 1.00keV-15keV. A standard Fixed Point Multiplication (FPM) algorithm was used to calculate the concentration of oxides in all samples. This concentration set was used to build a data set for PCA and PLSDA. Correlation between classifications based on spectral analysis and concentration analysis will be shown. Raman spectra were collected in the range of 100cm-1-3500cm-1 and MVA was applied to these spectra to extract differences in connection with geolocation. The data show that MVA allows clear differentiation of samples; for example, from the east or west coasts of the United States or from the United States, Europe, or the Middle East. PCA and PLSDA models for the east and west coast data sets were created and show significant separation between the sand originating from different geolocations. Raman spectra of the materials show that the main feature is SiO_2, but other spectral features originating from different oxides allow the differentiation of samples collected from the different locations. Data fusion technology was applied to the set of XRF and Raman data to create PCA and PLSDA models. Misclassification in PLSDA models was studied using randomly selected samples from available data. The results of standard and data-fused analysis are compared and discussed. In conclusion, this study provides methods that allow the differentiation of samples without knowing the actual concentration of elements/oxides and, therefore, this approach does not require any calibration for material identification.

Sand, Glass, XRF

B85 Differential Sampling of Footwear to Separate Alternative Particle Signals

David A. Stoney, PhD, Stoney Forensic, Inc, 14101-G Willard Road, Chantilly, VA 20151; and Paul L. Stoney, MBA, 14101-G Willard Road, Chantilly, VA 20124*

After attending this presentation, attendees will understand the method and potential contribution of the differential sampling of footwear as a means of separating sets of small particles that have accumulated as a result of exposures to different environments at different times.

This presentation will impact the forensic science community by providing an efficient, practical method to separate loosely, moderately, and tightly held particles from the surfaces of footwear. The inter-comparison and subtraction of these different particle sets will provide a means to separate alternative particle "signals" (as, for example, when subtracting a background spectrum in Infrared (IR) spectroscopy).

The separation of particle signals arising from different sources is one of the enabling operations for Particle Combination Analysis (PCA).[1] Although it is well recognized that criminals track dusts to and from every crime scene, dust particles on a suspect's shoes are very seldom used as evidence linking the accused to the crime. The major obstacle preventing the use of this type of evidence is that the shoes have mixtures of particles arising from activity before, during, and after the crime itself.[2] Methods separating the evidentiary particle "signal" from background noise would enable a powerful new and widely applicable forensic capability. This capability would augment traditional footwear pattern evidence with objective quantitative associations, addressing one of the specific issues raised in the 2009 National Academy of Sciences (NAS) Report, Stregnthening Forensic Science in the United States – A Path Forward. To help pursue this possibility, methods have been developed and tested that employ a series of successively more aggressive particle sampling protocols to separate loosely held, moderately held, and tightly held particles from the surfaces of footwear.

Two distinctly different and commonly encountered types of shoe soles were used in this study: athletic shoes (with flexible rubber soles) and work boots (with hard rubber soles). Eighteen new pairs of shoes of each type were sequentially exposed by walking a distance of 250m in three outdoor environments. Environments were evaluated and selected based on a well-defined accessible path and the presence of particle populations that were: (1) individually diverse; and, (2) collectively distinguishable from one another by defined qualitative and quantitative particle characteristics. Separate pairs of shoes were used for single-environment exposures (12 pairs, 6 of each type, 2 for each of the 3 environments) and sequential exposures to all three environments (24 pairs, 12 of each type, 2 for each of the 6 alternative sequences). Following exposures, particles from the outermost surfaces of the footwear soles were harvested by three progressively more aggressive methods: walking on paper (12 steps on butcher paper); electrostatic lifting (six lifts using a commercially available electrostatic lifter); and surface swabbing. Swabbing was conducted using lint-free clean room swabs moistened with 2% pre-filtered aqueous ethanol, resulting in particle suspensions. Particles on the paper and electrostatic lifts were collected using the same swabbing procedure, resulting in similar particle suspensions. Particle suspensions were fractionated by sieving and settling to recover fine sand and silt-sized particles. Particle types and quantities were measured by point counting using polarized light microscopy.

For each of the pairs of shoes, and for each of the successively more aggressive sampling methods, fine sand and silt-sized particles were recovered in sufficient quantities for quantitative analysis and comparison of soil minerals by polarized light microscopy (n >300). Under the experimental conditions, athletic shoes (with flexible rubber soles) retained more fine sand and silt-sized particles than did the work boots (with hard rubber soles).

The successful differential sampling of particles adhering to footwear surfaces enables the comparison of particle populations that adhere with different tenacities, allowing the development and exploitation of methods that can recognize different particle signals occurring simultaneously on these surfaces. Differential sampling also allows more fundamental investigations of phenomena contributing to the transfer and persistence of small particles on footwear.

This project was supported in part by an award from the National Institute of Justice, Office of Justice Programs, United States Department of Justice. The opinions, findings, and conclusions or recommendations expressed in this presentation are those of the authors and do not necessarily reflect those of the Department of Justice.

Trace Evidence, Footwear, Particle Signals

B86 Total Imaging Analysis of Paint

Roger Kahn, PhD, Harris County Institute of Forensic Science, 1885 Old Spanish Trail, Houston, TX 77054; and William M. Davis, PhD, 1885 Old Spanish Trail, Houston, TX 77573*

After attending this presentation, attendees will understand a new approach to the analysis of paint samples (or any lamellar exemplars).

This presentation will impact the forensic science community by demonstrating an alternative approach to paint analysis which may then become available in additional laboratories.

The analysis of paint evidence has a long history as a subdiscipline of trace evidence. Automotive paint, in particular, can be probative in hit-and-run cases. These paints are analyzed for their class properties and can be cross-referenced to databases such as Paint Data Query (PDQ). Routine paint analysis involves optical characterization of component layers followed by chemical analyses of those layers via vibrational spectroscopy (Infrared (IR) and Raman), pyrolysis gas chromatography, Scanning Electron Microscopy with Energy Dispersive X-ray (SEM/EDX) analysis, and Laser-Induced Breakdown Spectroscopy (LIBS), to name a few. Many of these are non-destructive, inducing little damage to original evidence.

Recent advances in IR imaging provides the paint examiner with a new tool. Particularly useful are instruments that have the capability to capture microscopic IR images with a Total Attenuated Reflection (ATR) device. These devices allow for better energy throughput to the sample than traditional IR microscopes. It should be noted that all of these devices collect data using interferometers (Fourier Transform). IR techniques alone assist in the identification of the majority of organic components of binders and extenders as well as some inorganic components. Inorganic components not captured with IR may be found in an X-ray analysis using SEM/EDX.

Traditionally layer characterizations (e.g., number of layers, colors, and dimensions) are performed by optical microscopy. Difficulties may arise when adjacent layers appear as the same color and cannot be observed with visible light, whether polarized or not. These layers may become apparent when using various light sources, although these manipulations tend to be subjective in nature and prone to artifact. Alternative contrast sources have been shown to help develop the number of layers in a paint sample, one of which is backscatter electron detection in an SEM.

Results will be presented of a paint analysis scheme which not only takes into account the visible images but images in the IR and X-ray regions. One acrylic mounted paint chip can be used throughout the experimental process. The IR images are color-enhanced representations of IR space in which each pixel represents an IR spectrum in the energy range of $4{,}000^{-1}$-750 cm^{-1}. X-ray maps of constituent elements are provided for each sample alongside a back-scatter electron detection image of the lamellae. The maps are acquired using a variable pressure option on an SEM and hence no sample preparation is required to avoid charging of the sample and image degradation over the course of the map acquisition. Validation samples will be provided that show structural and spectroscopic replication of known PDQ samples.

The techniques discussed in this presentation may be extended to other lamellar materials such as food packaging.

Paint, FTIR Imaging, X-Ray Mapping

B87 When Are Variations in Duct Tape the Result of True Differences? A Cautionary Tale

Diana M. Wright, PhD, FBI Laboratory Division, Chemistry Unit, Rm 4220, 2501 Investigation Parkway, Quantico, VA 22135*

After attending this presentation, attendees will understand two scenarios in which observed variations between duct tape samples were evaluated independently and produced different conclusions regarding an association. This information may be helpful in interpretation of a comparative duct tape analysis and in assessing the significance of those results.

This presentation will impact the forensic science community by increasing knowledge of the variation that can occur between mass-produced materials, specifically those manufactured by the same producer using similar technologies. The effect these results may have on association/discrimination criteria will be discussed.

Duct tapes are a type of trace evidence commonly encountered in North American forensic laboratories. Techniques used to analyze duct tapes can readily discriminate different products, even those from a single manufacturer. Even minor physical (e.g., backing film thickness) or compositional (e.g., intensity variation in filler components) differences may be justification to discriminate tapes.

In this presentation, differences observed in the Fourier Transform Infrared (FTIR) spectroscopy data of duct tape samples manufactured by the same company will be discussed.

In the first example, results of a duct tape homogeneity study will be presented in which samples taken from different sections of the same 60-yard roll were determined to be statistically different; however, these differences were not considered to be significant when spectral overlays were evaluated by a trained forensic examiner. Rather, it was determined that sample thickness differences were likely to be the cause of the differences that were reported by the statistical analysis.

The second example arose from a commercially available proficiency test in which an adhesive residue sample was compared to two partial rolls of duct tape. According to information later obtained from the test provider and the tape manufacturer, these rolls were different products manufactured by the same company but marketed to different do-it-yourself home goods stores using different labeling. The rolls were readily distinguishable by film thickness, a parameter not able to be assessed for the adhesive residue. Therefore, the examiner compared the residue to both rolls using the analytical suite routinely employed for duct tape comparisons: physical characteristics, FTIR, Scanning Electron Microscopy with Energy-Dispersive X-ray Spectroscopy (SEM/EDS), and X-Ray Diffraction (XRD). Based on this testing, the adhesive composition of both rolls and the adhesive residue sample were concluded to be analytically indistinguishable by the examiner. Minor intensity differences in the FTIR data between the two rolls were noted and attributed to possible sample thickness variation in sampling. After the results were submitted, the test provider reported that the residue was attributable to only one of the submitted rolls.

The examiner submitted the test samples to the tape manufacturer for analysis and assessment. Subsequent discussions indicated that the observed intensity differences may have been the result of a different processing method, which could explain the differences in the FTIR data as true concentration differences.

It is anticipated that the results of this study might serve as a cautionary tale regarding the interpretation of any possible differences in manufactured, mass-produced materials. This discussion illustrates the need to better define the association/discrimination criteria that should be used in comparative duct tape analyses. The samples discussed in these examples were all pristine cuttings from new rolls of duct tape. Evidentiary duct tape samples have varying conditions and degrees of cleanliness, which would further factor into assessing the significance of any possible differences.

The language used to report the association/false inclusion will be provided to further illustrate how the use of qualifying statements, interpretation models, and justification for the strength of an examiner's reported opinions are necessary and beneficial to the process of interpreting a comparative analysis report.

Duct Tape, Variation, Interpretation

B88 Intra-Roll and Intra-Product Variations in Duct Tapes

Andria H. Mehltretter, MSFS, FBI Laboratory, Chemistry Unit, 2501 Investigation Parkway, Quantico, VA 22135; Diana M. Wright, PhD, FBI Laboratory Division, Chemistry Unit, Rm 4220, 2501 Investigation Parkway, Quantico, VA 22135; and Michael A. Smith, PhD, 2501 Investigation Parkway, Chemistry Unit, Quantico, VA 22135*

After attending this presentation, attendees will better understand the variation that can be expected within a single roll of duct tape as well as between rolls of those same tape products over time. This information may be used to better interpret the results of a comparative duct tape analysis and to assess the significance of those results.

This presentation will impact the forensic science community by increasing the knowledge of duct tape products, specifically the variation that can be observed/measured between tape products over an approximate six-month time frame (i.e., batch-level differences). The effect these results may have on association/discrimination criteria will be discussed.

Duct tapes are a type of trace evidence commonly encountered in North American forensic laboratories. Historically, the forensic community has relied on empirical observations, discussions with manufacturing representatives, and limited research studies to learn how and to what extent duct tape products vary. In order to provide a more robust understanding of duct tape variation, a two-part comprehensive study was devised.

Part 1 of this study examined how individual rolls of duct tape vary along both an individual roll's length as well as across a jumbo roll of duct tape. The jumbo roll analysis provided an evaluation of different rolls of the same product manufactured at the same point in time. It was determined that scrim count, width, thickness, and adhesive composition vary only to a limited extent along the length of an individual roll of tape. Further, aside from width, minimal variation in these characteristics occurs between different rolls cut from the same jumbo roll. Statistical analysis of the thickness and adhesive composition via Fourier Transform Infrared (FTIR) spectroscopy indicated that some statistically significant differences could be observed; however, these differences were minor and not meaningful in the context of the forensic examination of mass-produced products.

Following publication of those results, Part 2 of this study was undertaken in which the same manufacturers provided additional sample rolls of their most common products over an approximate six-month timeframe. Based on the results of Part 1, scrim count, width, thickness (both overall and film only), and adhesive composition (via FTIR) were further evaluated. Specifically, scrim count and width were measured to see whether any variation could be detected along the length of an individual roll, between rolls cut from the same jumbo roll, or between rolls produced at different points in time. Additionally, thickness and adhesive composition were evaluated to assess whether differences could be detected in these features between rolls produced at different times. When appropriate, multivariate statistical analyses were conducted on the data.

It is anticipated that the results of this study might be used to better define the association/discrimination criteria that should be used in comparative duct tape analyses. Further, an understanding of the variation over time can be used to determine whether forensic examiners can detect batch-level differences, which is important for interpreting the significance of an inability-to-discriminate result.

Duct Tape, Variation, Interpretation

B89 Hair Analysis: Learning From the Past and Moving Toward the Future

Sandra Koch, MS, Penn State University, Dept of Anthropology, Carpenter Bldg, Rm 403C, University Park, PA 16802*

After attending this presentation, attendees will better understand how the existing nomenclature used in microscopical hair analysis originated, the pressing need to revise how hairs are characterized for ancestry and root growth stage, and the significance of differences in microscopic characteristics present within hair structures.

This presentation will impact the forensic science community by emphasizing the need to standardize terminology and to promote an approach for microscopical hair examinations that is inclusive to the various disciplines studying hair today.

Microscopical and morphological analysis of hair occurred originally in anthropological studies of population groups in which racial classification was a primary concern. The methods and terminology used were then imported into medicolegal contexts and cosmetological research. As each field developed their unique analyses of hair, communication between fields declined. One of the unfortunate side effects was the continued use of outdated racial terminology in forensic hair examinations long after the terminology had been abandoned in anthropology. The more acceptable terminology currently being used outside of forensic hair examinations will be described with the goal of changing racial descriptors to ancestry-based groupings.

Correctly differentiating the growth stages of hair roots based on morphological characteristics and the presence of associated follicular tissue is important in forensic hair examination for determining whether a hair may be suitable for nuclear DNA testing or mitochondrial DNA. Unfortunately, different scientists look at an evidential hair and often differ in their classifications of root growth stage. This happens irrespective of experience so discussion will include the different growth stages, how they can be reliably differentiated, what examinations are most appropriate for these determinations, and the effects of conflicting growth stage categorization on forensic research.

Recent reviews of past hair examinations have focused on how laboratory results have been reported and used as the focus for testimony. Such reviews often have a positive outcome because they lead to improvements in how the discipline presents its findings and limitations. The various resources available through the Scientific Working Group for Materials Analysis (SWGMAT) and the Organization of Scientific Area Committees (OSAC) Materials (Trace) Subcommittee will be discussed, as well as certification, training, and research needs.

The field of hair analysis is in a state of transition, but with a careful review of the language used and what it means to others, a transparent evaluation of the evidence and the scientific basis for the results can be presented. With an interdisciplinary outlook, the field can more easily embrace change both in expression of results but also in application of new technology. By moving away from isolationist practices and research, hair analysis will continue to improve and remain relevant in forensic laboratories and research for years to come.

Hair, Telogen Roots, Ancestry

B90 Introducing New Instrumental Technologies in the Forensic Drug Laboratory — Learning From Past Experiences

Sandra E. Rodriguez-Cruz, PhD, Drug Enforcement Admin, Southwest Laboratory, 2815 Scott Street, Vista, CA 92081*

After attending this presentation, attendees will better understand the difficulties encountered when introducing new technologies into the laboratory.

This presentation will impact the forensic science community by presenting and discussing numerous factors affecting the introduction of new technologies into the laboratory and how those difficulties can be overcome by learning from past experiences.

Forensic laboratories responsible for the analysis of seized drugs must be equipped with the scientific infrastructure necessary for the qualitative and quantitative analysis of these materials. Minimum standards for the analysis of seized drugs have been published by the Scientific Group for the Analysis of Seized Drugs (SWGDRUG Recommendations Version 7.0; www.swgdrug.org). SWGDRUG recommends that laboratories implement analytical schemes involving the combination of Categories A, B, or C techniques, classified as such based of their maximum degree of discrimination. Depending on their legal jurisdiction, laboratories throughout the United States and abroad should implement analytical schemes to fulfill these minimum recommendations while providing the law enforcement and legal communities with accurate and timely results.

Depending on their analytical scheme and the suspected drug under investigation, analysts have the choice of utilizing a wide array of chemical and instrumental test procedures. Color and microcrystalline tests provide presumptive information, while instrumental techniques like Gas Chromatography/Mass Spectrometry (GC/MS) and Infrared (IR) spectrophotometry have become mainstays in the forensic laboratory because of their ability to provide structural information for a compound and, for most cases, a final identification. But these analytical techniques, although proven robust, do have limitations on their applicability.

New technologies are developed every few years that can improve the quality of forensic analyses and also potentially decrease turnaround times for results. Research and pharmaceutical laboratories are often the primary users of such new technologies, a result of the private nature of these industries, as opposed to the government-funded crime laboratories. With high caseloads and the continual appearance of new designer drugs, the need to introduce and establish these technologies in the forensic laboratory is essential; however, the introduction of new products and instrumentation sometimes proves to be a difficult task. This presentation will discuss some of the challenges faced when introducing these technologies into the crime laboratory. Examples of new technologies (Liquid Chromatography/Mass Spectrometry (LC/MS), Ultra High-Performance Liquid Chromatography (UHPLC), and Raman spectroscopy) will be discussed.

Some of the factors hindering the use and establishment of new analytical techniques in the seized-drug laboratory are obvious. The most often cited are lack of funding sources and the complacency among laboratory personnel; that is, the unwillingness to "try something new." Other factors are not often discussed, but they play equally important roles in the matter. Managers and analysts need to work together, be willing and comfortable about changing their "routine ways," especially when the alternative new technology can provide a higher-quality result in a faster manner. Even when laboratory personnel are willing to look into new technology, large backlogs and the lack of expertise may hinder their progress. Furthermore, managers and analysts are often overwhelmed by the information provided by instrument vendors, and quality assurance requirements and procedures are not always considered during vendor-laboratory discussions. Many times this results in laboratories acquiring instrumentation with much higher capabilities (and cost) than they realistically need. And finally, but certainly not less important, are the lack of training opportunities for analysts willing to use the new technology.

Criminalistics, New Technologies, Mass Spectrometry

B91 Embracing Change: Transitioning Pattern Evidence Research Into Forensic Science Operations

JoAnn Buscaglia, PhD, FBI Laboratory, CFSRU, 2501 Investigation Parkway, Quantico, VA 22135*

After attending this presentation, attendees will understand the essential factors for the successful transition of pattern evidence research into operational practice.

This presentation will impact the forensic science community by describing the key factors for insuring the successful transition of pattern evidence research into practice, as well as some of the impediments to such transition. Understanding the factors for successful transition will help forensic practitioners rapidly adopt new technology and will enhance the accuracy and reliability of forensic science.

Forensic science research and development efforts have seen a significant rise over the past decade, which may be attributed to many factors. The increased lay knowledge of forensic science and the "CSI effect" resulted in expectations of high-tech methods as "common practice" in forensic science; more universities began offering forensic science coursework and degree programs, which in turn focused more research attention on forensic science issues. The 2009 National Research Council of the National Academy of Sciences (NAS) Report, Strengthening Forensic Science in the United States – A Path Forward, which questioned the accuracy and reliability of some of the oldest and most renowned forensic science disciplines, specifically called for research to assess the scientific foundations of the pattern evidence disciplines.[1] Finally, more federal research funds became available for both basic and applied research in forensic science disciplines in light of the 2009 NAS Report.

However, increases in funding and research effort do not always yield a significant increase in useful products transitioned into operational practice. It is important to note that only a small fraction of research and development in most scientific endeavors ever reach successful completion, and an even smaller percentage are put into practice. With the forensic sciences receiving increased scrutiny as well as increased research resources, it is more important than ever to insure the successful transition of research products into the operational forensic laboratory.

Lessons learned from the transition of pattern evidence research into operational practice will be presented. Factors contributing to successful implementation as well as impediments to transition will be discussed using examples from research in latent prints and questioned documents. Examples of research transitions will include small, incremental changes to methods and practice, adoption of novel analytical methods, and research that provided foundational support for continued practice or significantly changed the analysis or interpretation of the discipline.

Research, Pattern Evidence, Criminalistics

B92 Implementing 3D Technology Into a 2D Philosophy

Heather J. Seubert, MS, FBI Laboratory, Firearms/Toolmarks Unit, 2501 Investigation Parkway, Quantico, VA 22135*

After attending this presentation, attendees will better understand some of the implementation hurdles that can be easily overcome for introducing new technologies and developing a strategy as to how to prepare for implementation.

This presentation will impact the forensic science community by providing an overview of integrating new technology into a science that hasn't seen much change in its methodology. This presentation will also inform the forensic science community about emerging technologies within comparative-based disciplines that are being evaluated for future casework applications.

The firearms/tool marks discipline can be traced back to the early days of the 1920s when early pioneers such as J.H Mathews, Calvin Goddard, and James Hatcher were exploring "forensic ballistics." In those early days of researching, many of their methods showed close parallels to the new technologies that are emerging relying upon measurements and illumination techniques. Also, the same question continues to motivate the practitioner to determine whether or not a bullet or cartridge case could be "identified" to a particular firearm. Even before the arrival of the comparison microscope, a match could be determined through the use of a filar micrometer, which was simply a special device placed at the top of a compound microscope and contained a scale and a cross hair, which moved along a scale. Another method used was the method of interchange. This method depended upon an illumination technique which involved a long camera set-up with a short lens.

Now, nearly 90 years later, these very principles of measuring and illumination that highlighted areas on bullets and cartridge cases then are being advanced to a level beyond the 2D world. These advancing technologies require the right approach for implementation and almost a strategy map for integration. The Firearms/Toolmarks Unit (FTU) of the FBI Laboratory has been evaluating and validating 3D technologies to enhance an identification conclusion with the desire to establish a qualitative and quantitative threshold which will introduce an objective component to this subjective discipline. Over the past two years, the FTU has acquired many of the advancing technologies available to the forensic science community in an effort to develop methodologies, build collaboration, and further the discipline of firearms and tool marks. The technologies the FTU has begun evaluating includes the Sensofar Confocal Microscope, the TopMatch Gelsight technology, the Alicona Focus Variation, and the EvoFinder. Over the course of this validation journey, the FTU has experienced challenges. This presentation will highlight some of those challenges (such as gaining acceptance from practicing examiners, fiscal forecasting for support from management, surviving technology hurdles) and will discuss how to prepare personnel to perform the evaluation and testing of these systems, setting up organized sample databases, preparing samples for testing, maintaining company support, estimating the fiscal projections for the continual maintenance and upgrades, building collaboration, and looking downstream to how the results generated will be articulated in a report of examination. And, finally, this presentation will examine how the community prepares for the legal challenges that will accompany the admission of these technologies in a court of law.

Validation, Legal Challenges, Technology

B93 The Transition From Research to Routine Use in the Forensic Chemistry Laboratory

Jose R. Almirall, PhD, Florida International University, Dept of Chemistry, University Park, Miami, FL 33199*

The goal of this presentation is to cover the scientific requirements, obstacles encountered, and collaborative spirit necessary to bring about the successful transition from the research laboratory to the routine operational laboratory.

This presentation will impact the forensic science community by assisting researchers to gain a perspective on the necessary operational requirements of forensic laboratories. Forensic laboratory personnel will learn what motivates researchers so both groups can better collaborate to bring research into routine usage.

The chemical analysis and comparison of a number of solid matrices of interest to forensic scientists are made possible by progression from fundamental research and method development, validation in several forensic laboratories, and the publication of international standards. The transition of high-sensitivity elemental analysis of materials, including glass from the research laboratory to adoption and routine use in a forensic laboratory is a slow and laborious process. This presentation will cover the scientific requirements, obstacles encountered, and collaborative spirit necessary to bring about the successful transition. Laser Ablation-Inductively Coupled Plasma/Mass Spectrometry (LA-ICP/MS) has been called the "gold" standard for solid-sampling and high-sensitivity elemental characterization of materials providing sub-ppm detection limits of elemental analytes encompassing almost 70% of the periodic table. In addition, LA-ICP/MS provides true *quantitative analysis* data that can be used in numerical/statistical hypothesis testing to determine "match" and also to populate databases that are useful to determine the probability of a match for a given elemental profile. Several forensic laboratories have collaborated on method development and optimization as reported by the European Union-funded Natural Isotopes and Trace Elements in Criminalistics and Environmental Forensics (NITECRIME) effort (2000-2005) and continued by the National Institute of Justice (NIJ) -funded Elemental Analysis Working Group (EAWG) effort (2008-2012).[1,2] The interlaboratory trials eventually resulted in high-quality performance of these methods for the analysis of glass in forensic laboratories and this effort culminated in the publication of international (American Society for Testing and Materials (ASTM)) analytical consensus standards for the examination of these materials.[3,4] More than 30 forensic laboratories around the world now routinely employ the use of LA-ICP/MS for materials characterization on every continent and the history of elemental analysis provides a good model on how forensic method development should progress from basic research to routine use and acceptance in the courtroom.

B94 The Future of Forensic Instrumental Methods of Analysis

Glen P. Jackson, PhD, West Virginia University, Dept of Forensic and Investigative Science, 208 Oglebay Hall, Morgantown, WV 26506-6121*

After attending this presentation, attendees will understand the current state-of-the art in instrumental methods of analysis and where the trends are likely to lead. Attendees will also gain an appreciation for factors that are likely to affect future trends.

This presentation will impact the forensic science community by providing practitioners with examples of technologies that have the ability to impact the way forensic analyses are performed. The possibility of performing on-site confirmatory tests has the ability to revolutionize the way forensic evidence is used and could result in criminal investigations being quicker and more efficient.

Instrumental methods of chemical analysis provide objective and largely irrefutable circumstantial evidence in the support of criminal prosecutions. Chemical measurements can also be archived for validation or cross-examination by third-party expert witnesses and are widely accepted as among the most reliable of forensic techniques; they received no criticism in the highly critical 2009 National Academy of Sciences (NAS) Report, *Strengthening Forensic Science in the United States — A Path Forward*. Several recent advancements in different technologies have resulted in a shift toward on-site and *in situ* chemical measurements, and the forensic community will have some important decisions to make regarding its future in this uncertain area.

This presentation will cover a variety of developments in instrumental methods of analysis that have the potential to impact the way forensic analyses are performed and will engage in discussion on the likely effects of their adoption into different levels of casework. For example, technologies can be incorporated at the crime scene or in the presence of suspects/victims, in remote vehicles, at booking, or in the crime laboratories. The point of analysis will influence the expertise of the instrument operator, the potential for contamination or mishandling, the relevance to evidence collection, and the relevance to the prosecutorial process. More specifically, the ability to identify substances in real time *in situ* can assist investigators with evidence collection and the prioritization of evidence. Similarly, the ability to identify suspected drugs before or during booking can assist with the accurate investigation of alleged crimes.

This presentation will also discuss some of the major concerns about the adoption of new technologies, including: (1) the expertise and ability of police officers to conduct chemical measurements; (2) the uncertainty or insecurity of laboratory-based drug analysts; and, (3) the ability of on-site measurements to withstand scrutiny in court.

Finally, this presentation will address some factors that are likely to influence the adoption of instrumental methods of analysis. These factors include the requirement for some brave game changers to set precedents with the adoption of new technologies and the requirement for a less conservative system or branch of practitioners who can adopt or propel such cutting-edge developments. The discussion of pros and cons of future technologies should not be construed as an endorsement or warning for change, but as an initiation for discussion as to how to prepare for this domain in the future of criminalistics.

Instrumentation, Analysis, *In Situ*

B95 Multi-Software Interpretation of Complex Mixture DNA Profiles: A Comprehensive Approach to Explaining DNA Interpretation Results in Courtrooms

Eugenio Alladio, MS, Centro Regionale Antidoping "A. Bertinaria," Regione Gonzole 10/1, Orbassano (Turin) 10043, ITALY; Paolo Garofano, MD, PhD*, Accademia Italiana di Scienze Forensi, via Manlio di Veroli, 3, Rome 00199, ITALY; Roberto Testi, MD, PhD, ASL Torino 2, Via Lessona 54/12, Torino 10145, ITALY; Marco Vincenti, MS, Centro Regionale Antidoping, Regione Gonzole 10/1, Orbassano, Torino 10043, ITALY; Denise Caneparo, MS, Regione Gonzole 10/1, Orbassano, ITALY; and Giuseppina D'amico, Regione Gonzole 10/1, Orbassano, ITALY*

After attending this presentation, attendees will understand how to use a multi-software probabilistic approach for Low Template DNA (LT DNA) mixtures in highly challenging samples to better explain evidence in court, avoiding expert discussion when using different interpretation strategies.

This presentation will impact the forensic science community by illustrating how diverse the results of different software can be and how to manage these results by providing the most conservative and reproducible data in order to deliver complete statistical information.

The goal of this study was to define a rigorous approach to LT DNA mixture interpretation using multiple probabilistic software programs. Despite several recommendations having been proposed over the past years concerning the importance of evaluating several factors which may affect inclusion or exclusion hypotheses from prosecutor or defense, a rigorous approach has still not been properly defined in order to establish a "universally accepted" methodology. Moreover, this lack of regulation and guidelines leads experts to differently interpret evidence in courtrooms by applying several statistic approaches, which are often incomprehensible to the jury and legal experts. This practice causes the ability to make a judgement "beyond any reasonable doubt" even more difficult. In order to improve judgement capability and impartiality, this study adopted two models: the semi-continuous approach (using LRmix Studio and Lab Retriever software) and the fully continuous approach (using Charles Brenner DNA•VIEW™ mixture solution software).

Both models helped to highlight the difficulties encountered when evaluating challenging Short Tandem Repeat (STR) profiles and clarified the need for extreme caution in order to achieve a correct interpretation of the DNA evidence as this can heavily affect the outcome of a trial. After thorough validation studies, this research developed the "statistic consensus approach." In practice, this approach compares all Likelihood Ratio (LR) values obtained from all software used. If all LR results are similar and convergent, then the most conservative LR value obtained is reported. On the contrary, if LR results are not similar, the interpretation process provides an inconclusive decision. This approach resembles, in a complex way, the consensus method itself, which makes use of alleles observed in different replicates.[1-3] Due to this approach, it seems possible to conclude that certain suspects under investigation are unquestionable contributors to LT DNA mixtures under investigation. Even though the application of several software programs and different models is questioned by some scientists, this approach has already been successfully tried in court. The presentation of results were made easier during the trial since this approach considers different advocated issues such as the level of conservatism, the semi-continuous model's comprehensibility, and the fully continuous model's complexity.[4] Actual cases using this approach will be presented.

LT DNA Mixture Interpretation, Statistical Consensus Profile, Probabilistic Software

B96 Threshold to Probabilistic DNA Profile Interpretation: Why Change?

Stuart Cooper, MSc, ESR, Private Bag 92021, Auckland 1142, NEW ZEALAND; Catherine E. McGovern, MSc, ESR, Private Bag 92021, Auckland 1025, NEW ZEALAND; Jo-Anne Bright, ESR Ltd, Hampstead Road, Auckland, NEW ZEALAND; Duncan Taylor, PhD, Forensic Science South Australia, 21 Divett Place, Adelaide 5000, AUSTRALIA; Damien Abarno, PhD, Forensic Science South Australia, 21 Divett Place, Adelaide 5000, AUSTRALIA; and John S. Buckleton, PhD, PB 92021, Auckland, NEW ZEALAND*

After attending this presentation, attendees will have expanded their knowledge base in relation to advances in DNA profile interpretation, particularly in the area of probabilistic interpretation methods. This presentation is intended to address the question: Why change from a binary/threshold-based method?

This presentation will impact the forensic science community by providing an overview of the changing science behind DNA profile interpretation and re-addressing the known shortcomings of current interpretation methods. The use of actual casework examples will help facilitate the transfer of knowledge.

There have been a number of recent reviews of laboratory practice that have resulted in negative media reports. These have led to some laboratories questioning their interpretation protocols and whether these are still fit for the purpose. One such review occurred in Australia in 2009 and resulted in the implementation of an Australasian consensus approach to profile interpretation. Since then, uptake of probabilistic software in casework has increased significantly around the world with many more laboratories currently investigating the move away from traditional threshold/binary based or combined probability of inclusion models.

A number of fully continuous probabilistic methods have been described that model allelic and stutter peak heights within a DNA profile. Such models can help address the known shortcomings of traditional methods of profile interpretation, such as those within a binary model.[1-3]

So, why change? This presentation will look back at traditional DNA profile interpretation methods and highlight known shortcomings. The use of probabilistic models and software will be shown to address these issues. This will demonstrate the power of such models and their ability to decrease rates of false inclusion and false exclusion for a range of profile types. In addition, results of previous studies demonstrating how the use of probabilistic software can, under certain circumstances, help facilitate a consistent approach to the interpretation and reporting of statistical findings in a given case will be provided.[4]

Actual casework examples will be provided, demonstrating the benefits which would not have been realized without the use of probabilistic software. These examples will hopefully allow attendees to visualize the advantages for actual casework samples and put the use of such models into context within the criminal justice system.

This presentation will conclude with a discussion of possible future directions for probabilistic software and the further benefits which this may yield.[5]

Probabilstic Interpretation, Continuous Models, Casework Examples

B97 Questioning the Unquestioned — Rethinking and Rejecting Traditional Mixture Concepts and Assumptions

Charles H. Brenner, PhD, 6801 Thornhill Drive, Oakland, CA 94611-1336*

After attending this presentation, attendees will appreciate that "contributor," "number of contributors," "allele present," "stochastic threshold," and other traditional mixture concepts are vague and not well-defined and, therefore, are not a solid foundation for mixture analysis.

This presentation will impact the forensic science community by highlighting pitfalls that are common to many or most mixture methods and which sometimes invalidate the results. Some remedies will be presented.

"Continuous" DNA mixture analysis is a big and welcome change from binary and other earlier methods, and with good reason it might be called a revolution or paradigm shift. A "mixture model" means a simplified description of DNA mixtures. A binary mixture model explicitly treats the mixture data as having just one dimension — for Short Tandem Repeat (STR) loci, it is the allelic repeat numbers. Phenomena such as dropout and stutter fit into the model awkwardly at best as ad hoc add-ons. A continuous mixture model acknowledges a full-fledged second dimension, namely the signal intensity or Relative Fluorescence Units (RFU) of each amplified allele. The extra ("continuous") dimension is modeled as a template amount randomly modified by the combination of amplification stochastic variation and injection sampling variation. Two dimensions instead of one is in an obvious sense a complication, but it also leads to simplification because it lets analysts model both dropout and most drop-in, as well as variations in peak height and stutter ratios in a coherent fashion simply as aspects of the same random variation rather than as multiple black boxes.

Like most changes, the continuous approach has arrived gradually through various intermediate stages such as "semi-continuous" methods and ad hoc ways to cater to possible dropout. Consequently, there was no dramatic moment at which it became obvious to re-evaluate the original assumptions. Now is a good time to question some of the unquestioned principles and concepts about mixture analysis, and doing so unearths some surprises.

"Exclusion," an ill-applied term, has been known as a charlatan for awhile. A suspect is non-excluded by one meaning of the word, then an exclusion probability is calculated using a different meaning. "Number of contributors" isn't a definable number in any practical sense, yet traditionally some mixture protocols wrongly instruct the analyst to begin by determining it. Furthermore, it need not be the same number for prosecution and defense, contrary to typical mixture protocols and software. Realistic examples will illustrate and explain substitute concepts, such as "degree of contribution," that make more sense.

Thresholds rarely have a natural role in the real world; "stochastic threshold" is a particularly unfortunate example as it was invented specifically for the analysis of *simple* stains and was borrowed even into binary mixture analysis only by mistake. In a continuous mixture model, it is natural to view all peak height ratios as more/less probable rather than yes/no possible. Hence, correcting the early mistake and banishing the "stochastic threshold" concept is a natural, though not inevitable, consequence of adopting a continuous mixture model.

In several ways, the continuous approach to mixture modeling tends to eliminate complication and encourages clear and explicit thinking about the analysis process; however, there are various ways to devise a continuous model and retaining some of the traditional misconceptions is possible. Critical analysis should begin with writing down the model. If that is done clearly, then assumptions can be better recognized and it will be easier to see misconceptions and know where to be wary.

Mixture, Pitfall, Continuous

B98 Demystifying Mixture Interpretation Software Tools (MIST) — Practical Applications and Implementation Strategies for DNA MIST

Patricia A. Foley-Melton, PhD, RTI International Center for Forensic Science, 3040 E Cornwallis Road, Bldg 3, Rm 201, Research Triangle Park, NC 27709; Jeri D. Ropero-Miller, PhD, RTI International, 3040 Cornwallis Road, PO Box 12194, Bldg 7, Rm 211, Research Triangle Park, NC 27709; and Lyndsie N. Ferrara, MS, Duquesne University, 600 Forbes Avenue, Pittsburgh, PA 15219*

The goals of this presentation are to: (1) investigate how DNA MIST have been used for crime laboratory applications; (2) provide considerations from current users to inform potential technology adopters; and, (3) assist with implementation planning by providing practical and technical considerations through examples of real-world applications.

This presentation will impact the forensic science community by informing forensic practitioners in crime laboratories of the potential benefits of these tools and supporting the decision-making process for adoption of this technology into forensic DNA crime laboratories.

This presentation will provide an overview of the reported landscape study of DNA mixture interpretation software tools conducted by the National Institute of Justice's Forensic Technology Center of Excellence at RTI International with support from Duquesne University.

Many crime laboratories have recognized the benefits of adopting a DNA mixture interpretation software tool that assists with the challenges of complex mixture interpretation and provides statistical analysis. Forensic DNA crime laboratories, therefore, benefit from a study that reviews current product offerings, features, and capabilities, and examines how this technology is chosen, acquired, implemented, and validated. Although probabilistic software tools can assist with many of the issues experienced with complex mixtures, it is important for laboratories to understand the features and limitations of the different tools and make a choice that best meets their needs.

The objectives of this study were to investigate to what extent DNA mixture interpretation software tools have been used for DNA forensic crime laboratory applications, provide considerations from current users to inform potential technology adopters, and assist with implementation planning by providing practical and technical considerations through examples of real-world applications. This study captures the current state of DNA mixture interpretation software tools and the potential benefits of adoption. The considerations and benefits described in this study were obtained through interview discussions with subject matter experts, including crime laboratory practitioners, stakeholders, technology developers, academics, and key decision makers. The captured discussions highlight the different needs and methods for procurement, validation, and implementation. This study also contains a comprehensive review of secondary sources, such as journal and industry literature, for information related to need, successful use, developmental validation, and adoption criteria. In addition, the key considerations for successful implementation are discussed, including comprehensive training on the software and the underlying mathematical model, the resources needed for internal validation, including planning, labor, and time, and the potential for additional support from the laboratories' Information Technology (IT) departments.

With the continued increase of complex mixture data, the need for mixture interpretation software tools is of growing importance to the forensic DNA community. Given the availability of open-source and commercial software options, forensic DNA crime laboratories must assess their needs to find the most suitable software tool.

DNA, Mixture, Software

B99 A Hybrid Machine Learning Approach (MLA) for DNA Mixture Interpretation

Michael Marciano, MS, Forensic and National Security Sciences Institute, Syracuse University, 1-014 Center for Science and Technology, Syracuse, NY 13244-4100; and Jonathan Adelman, MS*, Syracuse University, CST 1-014, 100 College Place, Syracuse, NY 13244*

After attending this presentation, attendees will better understand machine learning approaches and the potential impact of applying machine learning to aid in the interpretation of DNA mixtures.

This presentation will impact the forensic science community by introducing the novel approach of incorporating machine learning as an analytical tool for DNA mixture deconvolution. In addition, its utility will extend past the current capillary electrophoresis-based data to utilize sequence data. This approach will produce highly informative, reliable intelligence or investigative leads from complex DNA mixtures that currently cannot be interpreted via other methods.

The challenge of DNA mixture interpretation is at the core of forensic genetic identification. Mastery of this interpretation can significantly impact the course of criminal investigations and/or quality of intelligence. In forensic settings, scientists responsible for mixture interpretations have relied on data from empirical validation studies, computation, and experience. Limitations are inherent in human-based analyses while other deficiencies are specifically related to computational capacity complexity and time constraints. There are expansive data sets that may be computationally leveraged to better address DNA mixture deconvolution; a classification approach capable of extracting maximum information from those data sets may be better able to interpret complex mixtures.

An MLA is ideally suited to such complex data sets and can indeed be used in classification problems. Hybrid systems capable of combining "human-like" subjective reasoning with the computational power of artificial intelligence techniques may be of special interest. These MLAs may provide higher-confidence and more rapid and expanded deconvolution capabilities. The power in such a system stems from: (1) the ability of the algorithm to learn from an initial data set and subsequently classify mixtures from previously unseen data; and, (2) the influence from the human analyst's experience-derived "rule sets." The approach utilizes the strengths of both computationally intensive algorithms and expert systems. Candidate features such as peak height and ratios were identified for extraction from mixture data sets, and the subsequent evaluation will be used as the feature vector used as input for the machine learning algorithms.

Several MLAs will be evaluated, with training data drawn exclusively from mixtures of known contributors and proportions. Once trained and validated, the chosen MLA will have the potential to rapidly (within minutes) deconvolute increasingly complex mixtures of at least three contributors. The architecture of the MLA permits mixture analyses using diverse data types including DNA fragment data, Polymerase Chain Reaction (PCR) amplification parameters, and a wide array of instrument parameters. The data-agnostic structure will allow increased flexibility in adapting to analyses of new data types, such as next generation DNA sequence data.

DNA Mixture, Machine Learning, Deconvolution

B100 Separating DNA Mixtures by Computer to Identify and Convict a Serial Rapist

Mark W. Perlin, PhD, MD, Cybergenetics, 160 N Craig Street, Ste 210, Pittsburgh, PA 15213;and Garett Sugimoto, MS*, Kern Regional Crime Laboratory, 1300 18th Street, 4th Fl, Bakersfield, CA 93301*

After attending this presentation, attendees will understand some principles of using probabilistic genotyping separation of complex DNA mixtures to investigate serial crime, calculate match statistics, prepare for trial, establish genotyping reliability, and present computer results in court.

This presentation will impact the forensic science community by providing a case example of using sophisticated computer technology that resolves complex forensic evidence in order to simplify human understanding and the communication of statistical support.

In July and August of 2013, a masked man broke into four separate Bakersfield, CA, homes and assaulted nine women and children. Three women were raped and one child was molested. The police recovered biological evidence from three of the crime scenes.

The Kern Regional Crime Laboratory (KRCL) took 37 swabs and cuttings from garments, blankets, apartment surfaces, skin, body cavities, telephones, and zip ties. In October of 2013, KRCL tested these biological items with Identifiler® Plus to generate Short Tandem Repeat (STR) data. The items were largely low-level DNA mixtures of three or four people. Human review of this data was generally uninformative; however, one of the zip ties (found in the road outside a victim's apartment) was a DNA mixture with a clear major contributor. This major donor led to a Combined DNA Index System (CODIS) profile that identified gang member Billy Ray Johnson.

Mixture separation and comparison were performed on all 37 evidence items using TrueAllele® Casework probabilistic genotyping technology. The company and KRCL independently conducted this mixture interpretation, each using their own in-house computer.

In October, the company interpreted the 37 evidence items by computer, separating the mixtures into genotypes. Parallel processing permitted all the computer analyses to proceed simultaneously. Once the 11 reference samples became available, computer comparison between separated evidence and reference genotypes yielded match statistics that indicated inclusion or exclusion. The technology linked eight mixture items (purse strap, phone, phone cord, two pants, shirt, bathtub handle, and zip tie) to Johnson. The computer showed the mixtures also contained DNA from victims and other people, consistent with their statements. The company sent their case report on these findings to the Kern County District Attorney's office. A grand jury heard the DNA and other evidence in December of 2013. They indicted Johnson on 25 counts, and he was arrested.

Separately, the KRCL conducted an independent in-house TrueAllele analysis of the DNA mixture data. Their match statistics agreed with the company's results. The concordant inclusionary statistics ranged from hundreds to hundreds of quintillions, depending on DNA quantity.

At the 2015 trial, expert witnesses from the company and KRCL testified about their match results. Each group had independently calculated match statistics, arriving at the same conclusions regarding the individuals who had contributed their DNA to the crime scene evidence. The computer had dissected the mixtures to show who was (and wasn't) associated with each item.

The jury was informed about computer interpretation of DNA mixtures and viewed a PowerPoint® presentation that explained how a computer separates mixture data into contributor genotypes. Comparing a mixed evidence genotype that had been subjected to contributor separation by the computer with the reference genotypes, relative to a population genotype, visually clarified the match statistic. Using published validation studies, the expert witnesses established interpretation reliability and could give false positive rates for their statistical conclusions. The cross-examination was respectful of the science.

On April 21, a Bakersfield jury convicted Billy Ray Johnson of 24 (out of 26) felony charges. On May 19, the serial rapist was sentenced to life in prison without the possibility of parole plus 423 years. Computer technology had successfully analyzed otherwise "inconclusive" DNA evidence, helping to secure criminal justice and ensure public safety.

A case study will be presented in probabilistic genotyping as an example of the processing and presentation of complex mixture results. Familiarity with this approach will help criminalists obtain statistical results from low-level DNA mixtures containing three or more people and assist in explaining their findings in court.

DNA Mixture, Probabilistic Genotyping, Serial Rape

B101 Conceptual and Cultural Limitations Delaying the Transition to Probabilistic Genotyping in Forensic DNA Analysis

Mark R. Wilson, PhD, Western Carolina University, Dept of Chemistry/Physics, Forensic Science, Cullowhee, NC 28723*

After attending this presentation, attendees will better understand the current limitations affecting the transition to probabilistic genotyping in forensic DNA analysis.

This presentation will impact the forensic science community by providing an overview of current practices in Short Tandem Repeat (STR) mixture deconvolution and by contrasting some of these approaches to emerging methods.

The current culture of forensic science teaches us to think in binary (in/out or plus/minus) fashion. Often, the words that are used, including exclude, include, conclusive, inconclusive, match, identity, cannot exclude, etc., are treated as categorical absolutes rather than as proportionate, continuous, or semi-continuous concepts. This commonly accepted usage of terms within the field of forensic science does not serve us well in the real world of uncertainty and continuous variation, especially in cases where the evidentiary data are complex and difficult, if not impossible, to analyze without computer support. Due in part to training, it is difficult to throw away the binary method of thinking and fully embrace continuous reasoning — where certainty is correctly understood as applying within a context rather than absolutely — and uncertainty is embraced and measured rather than avoided.

Most approaches to STR mixture deconvolution have given at least some credence to a quantitative assessment of DNA mixture data, including those advocating thresholds and binary placement into categories; however, as time has passed, the binary approach has slowly been replaced by probabilistic reasoning that attempts to embrace data uncertainty rather than eschew it. So although the germs of these ideas have been present from the outset, they have only recently started to be fully appreciated.

All parties in this discussion agree that quantitative patterns are present in STR-based DNA mixtures, and that the goal of forensic interpretation should be to make full use of these data. Any deliberate restrictions imposed on the data will necessarily result in less than full use of the data. If potentially valuable information is discarded, then potential identification information is also lost, resulting in the potential for the DNA mixture to be considered as uninterpretable, which could result in the guilty remaining free and for cases to remain unresolved. Hence, justice is best served by utilizing the data in the most efficacious manner.

In fully probabilistic approaches to DNA mixture deconvolution, if the data itself are ambiguous, a properly validated computer program will express this ambiguity as uncertainty. This approach does not advocate for deliberate data rejection by applying thresholds that ignore data. If the data are uncertain, the program assigns less probability to particular outcomes, in effect spreading out, or diluting, the resulting probabilities of particular genotypes.

Fully probabilistic genotyping models are not constrained by thresholds and consider all of the genotype probabilities arising from the data. In order to estimate these probabilities, some approaches apply a hierarchical model with many integrated parameter variables, including peak heights, heterozygote peak imbalance, stutter, mixture weights, degradation, and noise.

Variance parameters in DNA mixture deconvolution can most accurately be estimated by using all relevant data, and ignoring relevant data necessarily reduces the accuracy of the estimates. This inevitably leads to higher uncertainty and less-definitive conclusions. Hence, there is no justification for deliberately discarding data, such as in the use of thresholds, nor is there any justification for invoking any "conservative" principles in STR mixture deconvolution, since once the appropriate variance parameters have been identified and modeled, a fully probabilistic approach provides a built-in protection from both overstated and understated conclusions.

A fully rational approach to mixture deconvolution holds that a high value of discrimination is always good. Importantly, efficient mixture deconvolution simultaneously affects both sensitivity and specificity and thus is good for both inclusions (sensitivity), and also for exclusions (specificity). The fully objective view places a great value on a wide separation between these two poles — because reducing uncertainty itself in forensic science is tremendously valuable.

This presentation will provide an overview of the conceptual and cultural limitations within forensic science to the adoption of probabilistic genotyping. Examples will be provided to emphasize the points covered.

DNA Mixtures, Genotyping, Probability

B102 Massively Parallel Sequencing — A Revolution for Complex Mixture Interpretation?

David Ballard, PhD, King's College London, 150 Stamford Street, London SE1 9NH, UNITED KINGDOM; Laurence A.E. Devesse, MA, King's College London, 4.124 Franklin Wilkins Bldg, 150 Stamford Street, London SE1 9NH, UNITED KINGDOM; Athina Vidaki, PhD, King's College London, 150 Stamford Street, Franklin Wilkins Bldg, London SE1 9NH, UNITED KINGDOM; Gabriella Mason-Buck, MSc, King's College London, Franklin Wilkins Bldg, 150 Stamford Street, London SE1 9NH, UNITED KINGDOM; and Denise Syndercombe Court, PhD, King's College London, 150 Stamford Street, London SE1 9NH, UNITED KINGDOM*

After attending this presentation, attendees will appreciate the potential that sequence analysis of Short Tandem Repeats (STRs) via massively parallel sequencing methodologies has to alter the way forensic science deals with complex DNA mixtures.

This presentation will impact the forensic science community by demonstrating that DNA mixtures currently believed to be of little evidential value may now be usefully analyzed due to the improvements in sequencing and statistical interpretation methodologies.

Complex DNA mixtures are often encountered during forensic casework; however, interpretation of these mixtures can be problematic and contentious. Advances achieved through novel software solutions underpinned by complex statistical methodologies have shown promise to improve this analysis. Further advances with the potential to substantially aid mixture interpretation are now available due to the enhanced ability with next generation sequencing/massively parallel sequencing to analyze not only the allele length but also the allele sequence and hence increase allelic discrimination.

The ForenSeq™ kit from Illumina® was released in mid-2015 and includes 58 autosomal, Y and X chromosome STRs along with 94 identity Single Nucleotide Polymorphism (SNP) markers all analyzed in one reaction. This provides an easily accessible way to attain the extra sequence data contained within STR repeats that cannot be extrapolated from the allele size alone.

A series of DNA mixtures containing two, three, and four contributors have been prepared and run in duplicate for both a standard capillary electrophoresis-based genotyping method and with the ForenSeq™ kit utilizing the Illumina® MiSeq® massively parallel sequencing platform. Mixtures have been run with final DNA input amounts of 500pg, 250pg, and 125pg to simulate a range of scenarios that might be typically encountered during forensic casework and explore how the stochastic amplification problems associated with low-level DNA impact the efficacy of mixture analysis.

Data analysis for the ForenSeq™ results was undertaken with the provided Illumina® universal analysis software suite to determine the STR allele repeat sequence, and additionally from the raw data using a bespoke bioinformatics pipeline that allowed further analysis of any SNPs present within the Polymerase Chain Reaction (PCR) flanking regions. Freely available continuous and semi-continuous mixture interpretation models have been used to evaluate the DNA mixtures with respect to a set of suspect/victim reference profiles providing a likelihood ratio relevant to the hypothesis.

This presentation will assess what benefit the knowledge of allele sequence data brings to this mixture interpretation process and how mixture interpretation, especially for complex touch DNA samples, may evolve in the near future.

Mixtures, Massively Parallel Sequencing, Interpretation

B103 The Power of Massively Parallel Sequencing for Complex Mixture Deconvolution and Other Forensic Applications

Sarah Cavanaugh, 10430 Furnace Road, Ste 107, Lorton, VA 22079; Katie Kennedy, BS, The Bode Technology Group, Inc, 10430 Furnace Road, Ste 107, Lorton, VA 22079; Michael N. Parsons, MS, 10430 Furnace Road, Ste 107, Lorton, VA 22079; Andrew B. Feldman, PhD, 11100 Johns Hopkins Road, Laurel, MD 20723-6099; Jeffrey Lin, MS, Johns Hopkins Applied Physics Lab, 11100 Johns Hopkins Road, Laurel, MD 20723; Jeffrey Becker, MS, Johns Hopkins Applied Physics Lab, 11100 Johns Hopkins Road, Laurel, MD 20723; Jon Davoren, MS, 10430 Furance Road, Ste 107, Lorton, VA 22079; and Donia Slack, MS, 10430 Furnace Road, Ste 107, Lorton, VA 22079*

After attending this presentation, attendees will learn of the multiple applications that massively parallel sequencing, or next generation sequencing, has for human identification and forensic investigations.

This presentation will impact the forensic science community by discussing complex mixture deconvolution through the sequencing of the Combined Offender DNA Index System's (CODIS's) core Short Tandem Repeats (STRs). The analysis of Single Nucleotide Polymorphisms (SNPs) for identity, phenotype, and ancestry on compromised or challenging evidentiary items will also be addressed.

With rapidly improving chemistries and decreasing cost, massively parallel sequencing has incredible potential for forensic investigations. Sequencing forensic STRs can overcome some of the limitations of genotyping by capillary electrophoresis and provides increased statistical significance with backward compatibility to size-based methodologies. The information provided by massively parallel sequencing can be invaluable for the deconvolution and analysis of complex DNA mixtures often obtained from forensic evidence, including items handled by multiple contributors and samples taken from rape cases involving multiple suspects. Additionally, this methodology allows for the analysis of large panels of other forensically relevant DNA markers, such as SNPs for identity, phenotype, and ancestry. These markers can be used to provide investigative leads and, due to their small size, can be exploited for use on highly degraded samples, such as aged evidence or skeletal remains.

Bode Cellmark Forensics, Inc. tested forensically relevant samples, such as handled documents, gun grips, tool handles, blood, semen, and saliva utilizing a novel sequencing kit and software solution as well as several commercially available next generation forensic kits; all specifically designed for use on the Illumina® MiSeq® platform. These techniques allowed for the analysis and data interpretation of massively parallel sequencing data of forensic loci of interest, from which the deconvolution of complex DNA mixtures was accomplished through the exploitation of SNPs within and immediately flanking STR loci. Additionally, the sequence variants analyzed provided an advantage over traditional capillary electrophoresis technologies by adding statistical power to match probabilities, forensic likelihood ratios, and paternity indices. In a panel of 92 individuals comprised of Caucasians, African Americans, Han Chinese, and Mexican Americans, D21S11 demonstrated a match probability of 1 in 23. By analyzing the SNP variants within and surrounding this locus, the match probability increased almost three-fold to 1 in 60. Furthermore, these samples were shown to be successfully typed for not only CODIS STR loci, but also SNPs for ancestry, all matching to the self-proclaimed ancestral origins of the donors.

Notably, the majority of samples sequenced were able to be successfully analyzed at the sub-nanogram level, including degraded blood and skeletal remains. The results of this comprehensive evaluation demonstrated the vast utility that massively parallel sequencing has for forensic applications, not only through the analysis of STRs, but also through the analysis of forensically relevant SNP markers for investigative leads.

Next Generation Sequencing, SNPs, Mixtures

B104 Differentiation of Individual Contributors in Contact Epidermal Cell Mixtures Using Fluorescently Labeled Antibody Probes, High Resolution Microscopy, and Flow Cytometry

Cristina E. Stanciu, BS, Virginia Commonwealth University, 1015 Floyd Avenue, Rm 2015, Richmond, VA 23284; Kate Philpott, JD, 9014 Falls Run Road, McLean, VA 22102; Ye Jin Kwon, MS, 640 Worcester Road, #502, Framingham, MA 01702; Eduardo E. Bustamante, BS, Virginia Commonwealth University, 1015 Floyd Avenue, Richmond, VA 23284; Tracey Dawson Cruz, PhD, Virginia Commonwealth University, 1015 Floyd Avenue, PO Box 843079, Richmond, VA 23284; and Christopher J. Ehrhardt, PhD, Virginia Commonwealth University, Dept of Forensic Science, 1015 Floyd Avenue, Rm 2015, Richmond, VA 23284*

After attending this presentation, attendees will understand the biochemical variation within epidermal cells across individuals and how this diversity can be coupled to antibody-based tagging procedures to differentially label contributors in a biological mixture. Attendees will also learn how flow cytometry and Fluorescence Activated Cell Sorting (FACS) may be used to rapidly characterize complex cell populations and physically isolate individual cell populations from a mixture sample.

This presentation will impact the forensic science community by introducing a new strategy for resolving touch mixtures that involves physical separation of cell populations before DNA analysis. This technique can assist forensic laboratories by providing an alternative to complex mixture interpretation procedures, thereby reducing analytical subjectivity and loss of evidence.

Analysis of contact or "touch" mixtures is a significant problem for DNA caseworking laboratories. The presence of cells from multiple contributors in an evidence sample can produce Short Tandem Repeat (STR) profiles that are difficult or impossible to interpret. Although many protocols for cell separation exist, most cannot be applied to mixture samples with only one cell type. New methods are needed that can differentiate epidermal cell populations from different contributors and allow them to be physically isolated prior to DNA profiling. One promising strategy for resolving complex cell mixtures is to target the diversity in protein structures in cells from different individuals. Differentially expressed proteins can be tagged with molecular antibody probes and used to label each contributor's cells in a mixture. Although this strategy is routinely used in biomedical applications, it has rarely been tested in a forensic context. Therefore, the goals of this study were to survey biochemical variation in epidermal cell populations and to identify specific protein targets that may be used to differentially label and sort individual cell populations from a touch mixture.

"Touch" epidermal cells were collected from ~20 individuals and characterized using high-resolution microscopy and flow cytometry. Analysis of unstained samples showed that the touch samples were composed of two distinct fractions: one containing keratinocytes ~30µm-50µm and the other composed of cell fragments/debris <10µm. Keratinocyte populations from each donor were isolated and hybridized to antibody probes targeting the Human Leukocyte Antigen (HLA) complex and cytokeratin filaments within the cell. Hybridization of epidermal cells with allele-specific HLA probes showed no discernable increase in fluorescence compared to unstained controls and subsequent experiments utilizing pan-HLA probes exhibited similar trends. This suggests that, unlike other cells types (e.g., White Blood Cell (WBC) and buccal cell), HLA antigens are either inadequately expressed or insufficiently reactive on epidermal cell surfaces to be a suitable target for cell labeling.

Next, epidermal cells were hybridized with cytokeratin probes AE1 and AE3 which target different sets of filament proteins. Fluorescence levels of AE1-hybridized cell populations showed significant differences across donors with median fluorescence ranging from ~700 to ~11,000 Relative Fluorescence Units (RFUs) and some donors showing as much as a two-fold increase in intensity over other individuals. Hybridization with AE3 probe showed similar trends with median fluorescence of cell population from different donors ranging from ~200 to ~600 RFUs. This indicates that AE1/AE3 antibody probes may be a useful tool for capturing biochemical variation between donor populations and differentially labeling cells in a mixture.

To test whether these biochemical differences could be used to separate cell populations in a forensic sample, touch mixture samples were labeled with AE1 probe and processed using FACS. Isolated cell populations were then subjected to STR profiling. Results showed that touch epidermal cells from different contributors could be labeled and then sorted, intact, with high efficiency into separate reservoirs (~95% of input cells captured). While partial to complete 23-locus STR profiles were obtained from the majority of sorted cell populations, DNA yields from these fractions vis-à-vis cell count suggest that intracellular keratinocyte DNA is highly degraded and that a significant portion of amplifiable DNA from contact epidermal samples may be extracellular. Thus, flow cytometry-based strategies for sorting the most challenging complex mixtures (i.e., mostly epidermal) may need to be coupled to sensitive DNA profiling techniques as well as workflows for processing the extracellular fraction of the mixture sample, which can easily be isolated during FACS for direct amplification.

Mixture Interpretation, STR Profiling, Flow Cytometry

B105 Cell Separation of Multiple Contributor Samples to Facilitate DNA Mixture Analysis

Nancy A. Stokes, MS, Virginia Commonwealth University, 1015 Floyd Avenue, PO Box 843079, Richmond, VA 23284; Cristina E. Stanciu, BS, Virginia Commonwealth University, 1015 Floyd Avenue, Rm 2015, Richmond, VA 23284; Christopher J. Ehrhardt, PhD, Virginia Commonwealth University, Dept of Forensic Science, 1015 Floyd Avenue, Rm 2015, Richmond, VA 23284; and Susan Greenspoon, PhD, Department of Forensic Science, 700 N 5th Street, Richmond, VA 23219*

After attending this presentation, attendees will better understand a possible new solution for simplifying Short Tandem Repeat (STR) genotyping of samples derived from multiple contributors. This technique involves separation of cells by the process of Fluorescence Activated Cell Sorting (FACS) prior to DNA extraction and amplification, thus enriching for contributors the resulting fractions and enhancing statistical strength of the genotyping analysis.

This presentation will impact the forensic science community by illustrating that forensic DNA evidence samples comprised of multiple individuals can significantly complicate interpretation of the resulting STR profiles and decrease the strength of the statistical analyses. In order to separate DNA sources within a mixture sample prior to STR analysis, FACS was utilized to segregate donor cells, based upon cellular characteristics of the contributors within the sample. The resulting separate fractions have reduced complexity, thereby facilitating STR analysis of the mixture sample.

FACS was utilized to separate contributor cells within Human Leukocyte Antigen (HLA) -labeled blood mock evidence mixture samples and mock touch evidence mixture samples based upon cell morphology. DNA was obtained from the mixture (presorted) and FACS sorted samples by the DNA IQ™ system. STR amplification was performed with the PowerPlex® Fusion System and resulting profiles were compared for the presorted and sorted samples. Genotyping was conducted manually for all profiles and by the probabilistic modeling program TrueAllele® Casework (TA) for selected profiles.

Presorted blood mock evidence mixture samples from three and four contributors yielded complex STR profiles. One of the sorted blood fractions from both three and four contributor mixtures showed enrichment to the level of one or two individuals. The other fraction was still a mixture but was less complex (i.e., at least one contributor was almost completely selected out). TA analysis of these presorted and sorted samples demonstrated enhanced statistical power post-sorting. Presorted samples for mixtures of individuals 105, 106, and 107 had similar log Likelihood Ratio (log(LR)) values for each contributor (9.86, 11.40, and 9.65, respectively). For the two FACS-sorted cell populations, TA analysis of fraction P2 produced a slightly higher value for contributor 106 (12.34) and excluded 105 and 107 (negative log(LRs) generated). TA analysis of fraction P3 produced a slightly higher value for 105 and nearly 11 orders of magnitude higher value for 107, respectively (10.13, 20.56) and excluded 106. Moreover, TA analysis of the sorted mixture from four individuals produced a log(LR) value to approximately single-source level (28.18) for contributor 103 in fraction P2. TA analyses thus confirmed and quantified observations by analyst genotyping that enrichment for individual contributors and increased statistical power may be accomplished with the use of FACS for cell sorting.

Mock epithelial touch evidence samples were analyzed as to whether the source of DNA was extracellular (free DNA), intracellular, or both. Intracellular DNA was isolated from pelleted and washed presorted cells and free DNA was collected from the supernatant of the washed cells and subjected to Microcon-100 concentration. Sorted cells yielded only intracellular DNA as the washes and sorting process removed free DNA from the sample. Polymerase Chain Reaction (PCR) quantification of presorted DNA showed that intracellular DNA was present, but the ratio of free DNA to intracellular DNA was approximately 2:1, though genotyping data were generated from both DNA sources. Epithelial samples were FACS sorted based on cell morphology (>20µm or <20µm). Six epithelial touch mock evidence mixture samples, each comprised of two or three contributors, were FACS sorted. The >20µm fraction yielded partial profiles for a single donor from two samples, inconclusive results from two samples, and no results from two samples. The free DNA yielded a full STR profile for a single donor from one of the samples, a partial single-source profile from four samples, and one sample failed to yield any results. These results demonstrate that FACS separation may be performed on touch evidence based upon cell morphology after additional protocol development and that at least a portion of the DNA from touch evidence is intracellular in origin.

Cell Sorting, Mixture Samples, Probabilistic Genotyping

B106 Separation of Compromised Blood Mixtures Using Fluorescence-Activated Cell Sorting (FACS) for Single-Source Short Tandem Repeat (STR) Profiling

Cristina E. Stanciu, BS, Virginia Commonwealth University, 1015 Floyd Avenue, Rm 2015, Richmond, VA 23284; Ye Jin Kwon, MS, 640 Worcester Road, #502, Framingham, MA 01702; Sarah R. Ingram, BS, Virginia Commonwealth University, 1015 Floyd Avenue, Rm 2015, Richmond, VA 23284; and Christopher J. Ehrhardt, PhD, Virginia Commonwealth University, Dept of Forensic Science, 1015 Floyd Avenue, Rm 2015, Richmond, VA 23284*

After attending this presentation, attendees will better understand how FACS coupled with Human Leukocyte Antigen (HLA) labeling may be used to resolve complex blood mixtures that have been degraded or compromised.

This presentation will impact the forensic science community by introducing a new method for separating contributors prior to DNA extraction, which can improve the efficacy of mixture interpretation in DNA caseworking units.

Previous studies have demonstrated that hybridizing cell mixtures with fluorescently labeled antibody probes and FACS can be an effective technique for separating certain types of cell mixtures. These include sperm and epithelial cell mixtures, where each cell can be easily differentiated based on their biochemical composition and morphological properties. Mixtures containing only one cell type have proven more difficult to resolve using this approach, especially when the mixture has been compromised and/or degraded. Sorting the cells from such samples has proven to be a challenge due to the complex chemical and physical changes associated with cellular decomposition, which lead to non-specific fluorescence and significant sample loss. The objective of this study was to develop new methods for labeling and sorting cells in compromised mixture samples and subsequently test them against samples approximating those encountered in forensic casework.

To accomplish this, a series of two- and three-person whole blood mixtures was created in which the total mixture volume ranged from 100µl-500µl, and each contributor was present in equal volume ratio. Mixtures were dried for 12 hours and then hybridized to antibody probes that targeted the HLA-A*02 allele. While flow cytometry analysis showed that dried samples experienced some cell loss, intact, immunoreactive white blood cells could be recovered from all samples (~300-13,000 cells). More importantly, when comparing flow cytometry results of one contributor's dry blood sample against their fresh whole blood sample, the dried blood sample showed similar binding specificity to the HLA-A*02 probe, such that A*02 positive donor(s) could still be resolved from negative donor(s) in mixture samples. Differences in the fluorescence intensity of HLA positive and negative contributor cell populations were subsequently used to define sorting criteria for isolating each mixture fraction. STR profiling was then performed to determine the sorting efficiency and assess the utility of this technique for forensic casework.

STR results from seven different mixtures showed successful isolation of both HLA-A*02 positive and negative contributors from each mixture. Profiles from the positive contributors were identical to their presorted, single-source profiles across 16 different loci. Allelic contributions from non-target contributor(s) was rarely observed, and, when present, was easily resolved from contributor alleles (10:1 to 50:1 contributor to non-contributor ratio). The sorted cell fraction from the HLA negative contributor showed similar results with STR profiles showing at least a ten-fold enrichment in contributor-specific alleles compared to the presorted mixture profile. Overall, these results suggest that HLA antibodies can be used to differentially label cell populations in a compromised blood mixture and, when coupled to FACS, cells from different contributors can be physically separated from a mixture to generate single-source STR profiles.

FACS, Human Leukocyte Antigen, Mixture Interpretation

B107 Development of a New DNA Screening System of Criminal Samples Using ForensicGEM™ and Adhesive Sheets

Shinichiro Akase, PhD, Forensic Science Laboratory, Kagoshima Pref.Police, Kamoike shin-machi 10-1, Kagoshima City, Kagoshima Prefecture 890-8566, JAPAN; Gregory S. Hummel, MS, Kansas City Police Crime Lab, 6633 Troost, Kansas City, MO 64131; Yasuhide Iwata, Forensic Science Laboratory Saga Pref.Police, Matsubara 1 Choume 1-1, Saga City 840-8540, JAPAN; Yuki Kariya, MS, Forensic Science Lab Kagoshima Pref.Police, 10-1 Kamoike shin-machi, Kagoshima City 890-8566, JAPAN; Takeshi Yoshikawa, Faculty of Fisheries, Kagoshima University, 4-50-20 Shimoarata, Kagoshima 890-0056, JAPAN; and Kazumasa Sekiguchi, PhD, 6-3-1 Kashiwanoha, Kashiwa 277-0882, JAPAN*

After attending this presentation, attendees will understand the concept of obtaining a simple idea from the everyday work of a criminalist and the importance of providing inter-agency training.

This presentation will impact the forensic science community by showing the practical possibilities of a new screening system.

For many years, numerous Short Tandem Repeat (STR) analyses have been performed on crime scene biological samples such as blood, saliva, and human body tissue. The information obtained from these analyses is utilized as evidence during criminal investigations. The high number of required analyses causes problems in terms of cost and labor for almost all crime laboratories. One reason for this is that it is impossible to know which analysis will be useful beforehand. In other words, many wasteful analyses are performed to obtain useful results. In a case with numerous blood stains from the offender and the victim, such as murder and injury, it is difficult to find the offender's blood without consuming a large amount of STR reagents and labor as there may also be several victims' stains, mixed stains, and degraded stains at the scene. If the positions of these different types of stains could be known before STR analysis, the number of target stains requiring analysis could be narrowed down. In order to simultaneously extract DNA from many samples present on crime scene material, such as a T-shirt, a new system was designed using a DNA extraction reagent (ForensicGEM™) and an adhesive sheet (polyvinyl chloride).

The essence of this system is as follows: (1) many samples are simultaneously collected on the adhesive sheet; (2) multiple DNA extractions are performed directly on the sheet by ForensicGEM™; (3) multiple DNA extracts are simultaneously subjected to quantitive Polymerase Chain Reaction (PCR); and, (4) the results of quantitive PCR are simultaneously indicated by computer graphic software.

In this study, basic experiments were performed to evaluate the efficiency and accuracy of this procedure for blood stains, saliva stains, and human body tissue samples. In conclusion, sufficient DNA can be extracted from blood and saliva in this manner, but body tissues were less effective. Both blind and situational tests were conducted with hypothetical samples. The results of these tests suggest the possibility of practical use of forensic DNA analysis in the field.

This presentation will also show the application of a bio-robot for attempting to move the solutions from the adhesive sheet to a 96-well plate automatically.

ForensicGEM™, Adhesive Sheet, DNA Screening

B108 Optimized Methods for Collection and Extraction of DNA From Archived Latent Fingerprints

April D. Solomon, BS, Virginia Commonwealth University, 4830 Valley Crest Drive, #202, Midlothian, VA 23112; Madison Hytinen, Virginia Commonwealth University, Richmond, VA 23220; Aryn M. McClain, BS, Virginia Commonwealth University, 1015 Floyd Avenue, PO Box 843079, Richmond, VA 23284; Marilyn T. Miller, EdD, VA Commonwealth University, 1015 Floyd Avenue, Rm 3001A, Box 843079, Richmond, VA 23284-3079; and Tracey Dawson Cruz, PhD, Virginia Commonwealth University, 1015 Floyd Avenue, PO Box 843079, Richmond, VA 23284*

After attending this presentation, attendees will understand the link between crime scene collection, visualization methods for latent fingerprints, and the success of laboratory analysis. The objective is to identify the best combination of DNA collection, extraction, and typing methods for treated and untreated latent fingerprints that were tape-lifted, secured on paper backing cards, and stored at room temperature for varying time periods.

This presentation will impact the forensic science community by providing more efficient collection and DNA extraction pairings, which are ready for immediate implementation, and by improving the success rate for obtaining probative Short Tandem Repeat (STR) profiles from tape-lifted archived fingerprints. Currently, the forensic DNA literature has not addressed this specific type of challenged sample.

Touch DNA samples have grown since the late 1990s due to advanced forensic technology, giving the potential to provide probative evidence for criminal casework, even in the absence of body fluids. Several studies have evaluated the best collection methods for latent fingerprints when DNA profiling is anticipated; others have separately reported DNA success from adhesives and from paper material. However, there is limited information on best practices for retrieving DNA from latent fingerprints sandwiched between adhesive and paper substrates.[1] Since these samples are often stored for long time periods, likely contain low template DNA, and end in failed analysis or lead to irresolvable mixtures, they are often overlooked as viable DNA evidence. Unfortunately, for many older cases, archived latent fingerprints collected in this manner may be the only physical or biological evidence available. With touch DNA consisting of corneocytes (dead skin cells) mixed with sweat and body oil, the potential for successful typing is high for these archived samples; however, data on success rates, optimized methods, and mixture prevalence is needed before laboratories agree to routinely process these samples.[2,3]

In this study, ten participants provided a set of latent fingerprints on both non-porous (glass) and porous (paper) surfaces. Fingerprints were treated with traditional powders for visualization, tape-lifted, and secured on paper substrates. Initially, single fingerprint cuttings were obtained and DNA recovery was assessed using four extraction methods (phenol-chloroform organic extraction, Qiagen QIAamp® Investigator kit, Invisorb® Spin Forensic kit, and ZyGEM® prepGEM™ Tissue kit). These findings confirmed that human cells (and thus, DNA) are retained on both the adhesive and paper sides of archived fingerprints. The paper substrate held more than three times as much DNA as the adhesive side. Thus, both the paper and adhesive sides should be processed in a combined procedure to improve DNA yields. Overall, the Investigator kit provided more detectable DNA than the other methods (53% of all samples tested). Respectively, DNA from the Invisorb® kit, ZyGEM® kit, and organic extraction provided detectable DNA from 43%, 23%, and 10% of all samples tested. Of the samples detected during quantitation, those processed with the Investigator kit provided the most consistent total DNA yields (1.643ng average); however, when visualization techniques were considered, results varied among the fingerprint treatments: magnetic treated, black carbon powder treated, and untreated fingerprints provided the highest DNA yield with the Investigator kit (2.00446ng average), organic extraction (0.6024ng average), and ZyGEM® kit (0.68322ng average), respectively. Thus, the visualizing technique performed at the crime scene may dictate which extraction will perform most efficiently when preparing archived fingerprints for DNA analysis. Interestingly, fingerprints processed using magnetic powder or black powder produced more detected samples and more DNA (on average) than untreated fingerprints. Based on this data, the Investigator kit was employed to evaluate the best methods for actually retrieving DNA from the paper and adhesive substrates of archived samples. Cuttings, a single-swab technique, and a double-swab technique were compared using multiple swab diluents (distilled water and 2% sodium dodecyl sulfate). Thus far, the double-swab technique is providing more than three times the DNA on average (0.497ng) than the single-swab technique (0.108ng) using water as the diluent.

In conclusion, this experiment will provide valuable information for forensic DNA examiners seeking to process archived fingerprints for DNA typing. The recommendations will be readily available for immediate execution to increase the likelihood of obtaining a full STR profile for casework. As such, cold cases with limited physical and biological evidence could be revisited with more confidence and less apprehension about these potentially compromised, low template DNA samples.

B109 Comparison of DNA Yield and Short Tandem Repeat (STR) Success Rates From Various Tissues in Embalmed Bodies

Amanda Wheeler, BS, 1105 Beasley Hills Lane, Houston, TX 77008; Natalia Czado, MS, 43 Virginia Avenue, Woonsocket, RI 02895; David A. Gangitano, PhD, Sam Houston State University, 13906 Paradise Valley Drive, Houston, TX 77069; and Sheree R. Hughes-Stamm, PhD, Sam Houston State University, Dept of Forensic Science, Huntsville, TX 77341*

After attending this presentation, attendees will understand some of the principles of genotyping chemically damaged and degraded tissue samples, such as those harvested from embalmed cadavers, for identification.

This presentation will impact the forensic science community by providing guidance concerning which tissues may be best harvested from embalmed bodies and those that will provide the highest quantity and quality DNA for human identification purposes in a timelier manner.

The process of formalin fixation is commonly used to preserve tissue sections for pathological testing and embalming cadavers for medical use or in preparation for burial. DNA extracted from formalin-fixed tissues may provide an alternative source of material for identification in forensic cases. Formaldehyde causes DNA damage and degradation, thereby reducing the quantity and quality of DNA available for downstream genetic analysis.

By analyzing the DNA yield, level of DNA degradation, and STR success of various tissues from embalmed cadavers, some guidance may be provided to forensic analysts regarding which samples from embalmed bodies are likely to generate more complete STR profiles.

In this study, tissue samples (N=122) were dissected from three male embalmed cadavers and included bone, cartilage, hair, muscle, internal organs, skin, teeth, and nail clippings. DNA was purified from all samples, the DNA quantity and level of degradation was determined using the QuantiFiler® Trio DNA Quantification kit, and genotyped using the GlobalFiler® Polymerase Chain Reaction (PCR) Amplification kit.

The results of this study, which showed a wide variation in DNA yield, degradation, and STR success between different types of tissues within each cadaver, and some variation between the three cadavers, will be presented. Overall, bone marrow samples resulted in the highest DNA yields, lowest DNA degradation values, and highest STR success; however, various muscle and skin samples also provided complete STR profiles, demonstrating that some soft tissues that are more quickly and easily harvested from embalmed cadavers can provide the same or greater DNA yields and STR success than the traditional, and more difficult to collect and process, bone and tooth samples.

When comparing tissues that experienced blood pooling (due to livor mortis) to tissues in regions that experienced compression, significantly more complete STR profiles on average were generated from the compressed tissues (62% versus 37% alleles recovered) (Analysis of Variance (ANOVA); p=0.02). These data support the thought that tissues affected by lividity may also experience greater exposure to formalin, resulting in DNA damage and reduction in downstream STR success.

Embalmed, DNA Damage, Tissue Sampling

B110 Standardized Kinship Data Test Set for Rapid DNA Validation

Stephanie DeDore, BS, 5200 S Merrimac Avenue, Chicago, IL 60638; Yvette Crandall, MS, BAE Systems, Inc, 16541 Commerce Drive, King George, VA 22485; Daniele S. Podini, PhD, Department of Forensic Science, 2100 Foxhall Road, NW, Washington, DC 20007; and Amanda C. Sozer, PhD, 4707B Eisenhower Avenue, Alexandria, VA 22304*

After attending this presentation, attendees will understand how the development of a standardized kinship data test set can be a simple and effective tool to aid in the validation of Rapid DNA kinship software. Attendees will also learn the planning and design strategies required for developing such a test set, enabling them to develop a test set for their own validation needs.

This presentation will impact the forensic science community by serving as a tool for a quick, simple, and effective method to validate the kinship software associated with Rapid DNA technology in preparation for field or laboratory DNA analysis operations. This validation tool will create standardization of the Rapid DNA platform's kinship functionality across all laboratories and fieldwork locations.

The Department of Homeland Security's (DHS's) mission is to protect America by preventing terrorism and enhancing security, managing the borders, administering immigration laws, securing cyberspace, and ensuring disaster resilience. While DNA is a powerful biometric, currently DHS does not have in-house DNA testing capabilities. Rapid DNA, a recent and important technology advancement in DNA testing, is designed to be utilized as a lights-out system with the ability to provide results within 90 minutes. This technology provides DHS with a portable, robust, in-house DNA capability. Rapid DNA technology for DHS kinship analysis was developed through a DHS Science and Technology Directorate (S&T) research and development effort that was part of a collaborative effort with the Departments of Defense and Justice. Through the use of Rapid DNA technology, DHS components may be able to prevent illegal and fraudulent immigration, deter human trafficking, identify disaster victims and reunite families, and identify criminals or terrorists attempting to enter the country. For this reason, the Rapid DNA kinship determination functionality will be of particular use to DHS.

The Rapid DNA kinship functionality will require validation and verification before the technology is put into operation and occasionally when the Rapid DNA software is updated or modified. In order to make the Rapid DNA kinship software validation and verification universal across all components of DHS, a robust kinship data test set has been created to enable quick and simple validation. When the Rapid DNA system is updated, the user can simply run the kinship data test set to ensure no errors or issues have occurred in the kinship analysis and statistical calculation process. When a kinship test is run on Rapid DNA, the results will show either inclusion or exclusion and the calculated relationship indices. The Rapid DNA user will be able to detect potential changes applied to the Rapid DNA kinship application and determine if the statistical analysis for the DNA profiles are reported properly.

Expanding on the National Institute of Standards and Technology's Standard Reference Family Data approach (http://www.cstl.nist.gov/strbase/kinship.htm), Common Message Format (CMF) files containing profiles associated with ten artificial pedigrees have been created. These pedigrees are specifically designed to include a wide number of alleles, including off-ladder alleles and microvariants. The kinship cases include biological relationship/kinship claims commonly encountered by the United States Citizenship and Immigration Services (USCIS) and Customs and Border Protection (CBP): standard mother/father/child trios, motherless, fatherless, grandparent-grandchild, siblings, and aunt/uncle to niece/nephew cases. The cases also include other DNA profile complexities (e.g., parent-wrong gender, mutations, null alleles, and rare alleles). The kinship data test sets incorporate the 20 common paternity index formulas identified by the American Association of Blood Banks (AABB). Testing of paternity index formulas for paternity trios and motherless cases are in accordance with the 2014 Appendix 4 of the AABB *Guidance for Standards for Relationship Testing Laboratories* 11th Edition.

Overall, this kinship data test set will provide not only DHS but all Rapid DNA users with a standardized validation tool allowing for easy implementation and validation of Rapid DNA technology as well as providing a resource for users to create their own kinship test set.

Rapid DNA, Validation, Kinship

B111 Development of a Microfluidic Differential Extraction Module and Refinement of Infrared (IR) -Mediated Short Tandem Repeat (STR) Amplification for a Rotation-Driven Microdevice

Kemper Gibson, 2230 E Teemont Court, Richmond, VA 23225; Jordan Cox, MS, 1823 Floyd Avenue, Richmond, VA 23220; Kimberly Jackson, 409 McCormick Road, Chemistry Dept, Charlottesville, VA 22903; James P. Landers, PhD, University of Virginia, Dept of Chemistry, McCormick Road, Charlottesville, VA 22904; and Tracey Dawson Cruz, PhD, Virginia Commonwealth University, 1015 Floyd Avenue, PO Box 843079, Richmond, VA 23284*

After attending this presentation, attendees will better understand the forensic applications of microfluidic platforms, micro Total Analysis Systems (μTAS), and recent advancements toward integrating a differential DNA extraction module for sexual assault samples.

This presentation will impact the forensic science community by describing a differential extraction module on a rotation-driven microdevice platform for sexual assault casework samples as well as refinement of IR-mediated STR amplification occurring on the device. If implemented, an automated device based on this microchip could remove the human variability often seen with manual differential extractions, speed the workflow for sexual assault samples, and result in high-quality data with fewer STR mixtures needing lengthy interpretation.

Microdevices offer several potential advantages over conventional methods for quick determination of STR profiles, including smaller reagent and sample volumes, less manual intervention, and decreased risk of contamination — all leading to decreased sample-to-answer time. IR-Polymerase Chain Reaction (PCR) and enzyme-driven DNA preparation have improved the ability of scientists to integrate microdevice modules that represent all aspects of the traditional forensic DNA workflow. While these technologies have the potential to significantly impact the way forensic science DNA laboratories function, extensive modification of these technologies is needed before microdevices can be implemented for processing casework samples. Commercially-available microdevice-based instruments (i.e., Remote Access Program for Interactive Diagnostics (RAPID)) require extensive external pumps and actuators for microfluidic control and are designed only for the processing of single-source reference (known) buccal swab samples. Unfortunately, forensic casework samples, ~52% of which involve testing of sexual assault evidence and which require a differential cell lysis process, are not currently amenable to microchip-based processing. Manual differential lysis is a time-consuming DNA purification process that often still results in mixtures, which require a significant amount of interpretation effort. As the media draws more attention to the number of rape kits left untested each year, it will become imperative that crime laboratories find ways to process more of these samples more quickly. To this end, the first goal of this project was the incorporation of a differential extraction module onto the aforementioned microdevice.

In this project, sperm cells were separated from non-sperm cells via an antibody-labeled, bead-based capture mechanism. Initially, chip architecture was redesigned to include an antibody capture chamber that allows for dual valving and microfluidic movement into side-by-side sperm cell and non-sperm cell DNA liberation chambers. This design allows for antibody-coated microbeads to selectively capture sperm cells, which would prevent movement through a burst valve designed to capture non-sperm cells. Next, two sperm-specific antibodies (SP-10 and SPAG8) and one male-specific antibody (MEA-1) were tested off-chip for binding efficacy using flow cytometry. To assure that other contributing female and epithelial cells were not binding to the sperm antibodies, two antibodies specific for epithelial cells were also used. Based on binding specificity and efficiency results from the flow cytometry data, the best sperm-specific antibody was selected for further on-chip testing.

The second objective of this work was to explore STR reaction chemistry alterations in an effort to improve STR profile issues often seen with IR-mediated amplification. Existing microdevice platforms that utilize rapid small volume IR-PCR and polymerase combinations often lead to the presence of significant non-adenylated (-A) products and an overall "ski-slope" effect that leaves alleles in the larger-sized loci either very low or undetectable by capillary electrophoresis. In previous studies, a commercially available primer set was used along with Phusion® Flash master mix and SpeedSTAR™ HS polymerases in a reduced volume reaction for IR-mediated on-chip amplification. In this study, AmpliTaq Gold® polymerase and AmpFℓSTR® Identifiler® Plus chemistry were evaluated, along with adjustments to the original combination of Phusion® Flash and SpeedSTAR™ HS, other enzyme combinations (AmpliTaq Gold® Fast and KAPA2G Fast), and longer final extension times. When used alone, AmpliTaq Gold® yielded negative Identifiler® Plus results; however, using it in combination with the Phusion® Flash-SpeedSTAR™ HS combination and a longer final extension (180s) resulted in a nearly complete profile (29 of 30 alleles called) with more than 40% of alleles (12 of 29) showing greater adenylated product. Additionally, none of the STR loci showed *only* -A peaks. Taken together, these improvements represent large strides toward the development of a sexual assault microdevice.

Microdevice, Differential Extraction, IR-PCR

B112 Direct Amplification and Commonly Encountered Crime Scene Substrates

Katelyn M. Gigl, BS, Penn State University, 107 Whitmore Lab, University Park, PA 16802; and Reena Roy, PhD, Pennsylvania State University, Forensic Science Program, 325 Whitmore Lab, University Park, PA 16802*

After attending this presentation, attendees will better understand how to obtain DNA profiles by direct amplification of bloodstains on substrates commonly encountered at crime scenes. Attendees will also learn that it is possible to obtain complete DNA profiles from body fluids without extraction or pretreatment of the stains.

This presentation will impact the forensic science community by providing information concerning how to generate DNA profiles within a very short time and without labor-intensive and time-consuming steps.

Items of evidence retrieved from crime scenes often contain blood. In order to generate Short Tandem Repeat (STR) profiles from such evidence, extraction, purification, and quantification prior to amplification of DNA is necessary. In this research, autosomal STR profiles were generated via direct amplification of bloodstains deposited on simulated crime scene substrates.

Blood samples from deceased males were collected in sterile tubes containing Ethylenediaminetetraacetic Acid (EDTA) to prevent DNA degradation and were kept frozen until ready for analysis. There were four stages in this study. The blood samples from the deceased donors were first extracted using the BioRobot EZ1 workstation and EZ1 DNA investigator kit in order to generate reference profiles. In the second stage, a measured volume (0.1µL) of blood was deposited on each of the ten substrates and dried for 24 hours at room temperature. The objects included: cigarette butt, drinking straw, dry brown leaf, woodchip, leather, and five different types of fabrics often encountered as evidence from crime scenes. None of these objects contained any lysing agent. Several of these objects contained potential inhibitors. The deposited bloodstains were punched using a Harris 1.2mm micro-punch on nine of the listed substrates. The tenth substrate, the woodchip, was too difficult to punch. Therefore, a minute piece approximating the 1.2mm punch was shaved off after depositing the blood on the woodchip. Each of the stains was extracted using the forensicGEM™ tissue extraction protocol. The samples generated from the two extraction methods were quantified and amplified using the amplification kits used for direct amplification.

In the next step of the project, each of these punched substrates containing the bloodstains created from 0.1µL of blood was amplified directly after pretreatment with reagents and buffer. All the substrates containing the stains were treated with the Prep-n-Go™ buffer prior to amplification with the GlobalFiler® Express Amplification kit. SwabSolution™ and PunchSolution™ were used for treatment of the stains prior to amplification with the PowerPlex® Fusion and PowerPlex® 18D Systems.

In the fourth and final stage of the research, each stain was amplified directly without any pretreatment with the reagents and buffer mentioned earlier. During the third and the fourth stages of this research, the substrates remained in the amplification reagents during the thermal cycling steps. Each bloodstain was amplified with the three direct autosomal STR amplification kits: GlobalFiler® Express Amplification kit, PowerPlex® Fusion, and PowerPlex® 18D Systems. Capillary electrophoresis was performed on a 3130xl Genetic Analyzer and data were analyzed using **GeneMarker**® software version 2.7.1.

Reference profiles were obtained from blood extracted using the traditional (EZ1 extraction) method. These profiles were compared to the profiles generated from the stains deposited on the various substrates and extracted with the forensicGEM™ tissue extraction protocol. The profiles were found to be concordant and consistent between and within each substrate and each amplification kit. These profiles were then compared to the profiles generated from each of the stains amplified directly with and without pretreatment as described in the third and fourth stages of the research.

Complete and concordant autosomal STR profiles were successfully obtained from the bloodstains deposited on the ten challenging substrates when they were amplified directly using GlobalFiler® Express Amplification kit, the PowerPlex® Fusion, and the PowerPlex® 18D Systems. The research indicated that the pretreatment of the bloodstains with the reagents and buffer did not enhance the quality of the profiles. Complete and concordant profiles were obtained when the stains were not subjected to any pretreatment and while the substrates remained in the reagents during the amplification steps.

At this time, the forensic community requires that forensic DNA analysts perform quantification prior to amplification. This study with direct amplification using simulated casework-type samples may be of limited value. Currently, with instruments such as the RapidHIT™ system from IntegenX® or the DNAScan Rapid DNA Analysis System from NetBio, analysts are already performing direct amplification of body fluids. It is expected that this procedure, which involves challenged substrates and direct amplification, would be acceptable in the near future.

Direct Amplification, STR, Crime Scene

B113 Tissue Preservation With Direct-to-Polymerase Chain Reaction (PCR) for DNA Profiling: An Alternative Disaster Victim Identification (DVI) Approach

Amy E. Sorensen, MSFS, 11 Webb Creek Place, The Woodlands, TX 77382; Clare Berry, BAS, National Centre for Forensic Studies, University of Canberra, Canberra, AUSTRALIA; David Bruce, PhD, NSW Forensic and Analytical Science Service, Weerona Road, Sydney, AUSTRALIA; Michelle Gahan, PhD, National Centre for Forensic Studies, University of Canberra, Canberra, AUSTRALIA; Sheree R. Hughes-Stamm, PhD, Sam Houston State University, Dept of Forensic Science, Huntsville, TX 77341; and Dennis McNevin, PhD, National Centre for Forensic Studies, University of Canberra, Canberra, AUSTRALIA*

After attending this presentation, attendees will be informed regarding the efficiency of various solutions to preserve DNA in fresh and decomposing tissue samples when stored in warm ambient temperatures for up to four weeks. In addition to the benefits of storing samples at room temperature, this presentation will also describe the results of combining these preservatives with direct-to-PCR amplification in order to process a high volume of tissue samples for faster DNA identification.

This presentation will impact the forensic science community by addressing the demands for DNA preservation in rapidly decomposing remains and providing faster DNA identification during a mass disaster. By directly amplifying DNA in solution (with dilution in some cases), DNA extraction from the dense tissues can be avoided and successful Short Tandem Repeat (STR) profiles can be obtained in a timelier manner.

Tissue preservation offers the ability to stabilize and isolate DNA from tissues in the field, far from a laboratory setting, where refrigeration may not be available. This has potential application to Disaster Victim Identification (DVI) as well as to any form of field-based forensic biological evidence or intelligence collection.[1] Forensic DNA analysis is one of the three primary methods of identification recommended by the International Criminal Police Organization (INTERPOL), together with fingerprint and dental analysis.[2]

Previous work has demonstrated the ability to obtain full STR profiles from DNA extracted from fresh muscle tissue preserved in Tris, EDTA, NaCl, Tween 20 (TENT) buffer, salt-saturated DMSO-EDTA solution (DESS), and two proprietary preservatives: DNAgard® from Biomatrica® and one from DNA Genotek, Inc.[3] Three of the preservatives (DESS, DNAgard®, and DNA Genotek) also yielded full profiles from DNA extracted from aliquots of the preservative solution surrounding the muscle tissues. Therefore, in this study, the possibility of obtaining DNA profiles without DNA extraction, by adding aliquots of preservative solutions surrounding fresh and decomposing human tissue samples directly to PCR, was explored.

The results of this work, in which full PowerPlex® 21 and GlobalFiler® STR profiles were obtained from fresh and decomposed tissue preserved at 35oC for up to 28 days, as well as from fresh tissue which had been stored at 35oC for up to 28 days, and then at -80oC for four years, will be presented.

DNA Preservation, Direct-to-PCR, DVI

B114 Enhanced DNA Extraction Via the Reduction and Alkylation of Disulfide Bonds by Iodoacetamide (IAM) and Tris(2-carboxyethyl)phosphine (TCEP)

Megan E. Grimes, MFS, 5187 Salt Pond Place, Woodbridge, VA 22193; Leah E. Willis, PhD, 2501 Investigation Parkway, Quantico, VA 22135; Jodi A. Irwin, PhD, 2501 Investigation Parkway, Quantico, VA 22135; Tamyra Moretti, PhD, Nuclear DNA Unit, FBI Laboratory, 2501 Investigation Parkway, Quantico, VA 22135; and Mark F. Kavlick, BS, 2501 Investigation Parkway, Quantico, VA 22135*

After attending this presentation, attendees will understand the importance of reducing and alkylating reagents during forensic DNA extraction, how the selection of these agents can increase DNA yield, and how to incorporate them into a typical casework workflow.

This presentation will impact the forensic science community by providing methods to significantly increase DNA yield from various forensic specimen types (i.e., blood, hair, semen, and calcified tissue) through the use of novel reducing and alkylating reagents which facilitate the breakage of and/or prevention of disulfide bond reformation in cellular proteins during DNA extraction.

Dithiothreitol (DTT) is a key reducing agent used in forensic DNA extraction that facilitates the isolation and purification of DNA from proteins in a biological specimen. DTT reduces protein disulfide bonds to thiols, thereby facilitating protein digestion by proteinase K and permitting the release of DNA from protective and/or contaminating proteins. For example, the unique membrane of spermatozoa, which is rich in disulfide bonds, requires a particularly strong reducing agent to lyse these cells and extract their DNA. Reducing agents are also employed when extracting DNA from hair shafts which are largely composed of keratin, a structural protein which contains myriad disulfide bonds.[1-3]

When using a reducing agent such as DTT, which produces a disulfide exchange, disulfide bonds may reform and may, in turn, reduce DNA yield and/or purity. To prevent such reformation, an alkylating agent, IAM, may be employed in conjunction with DTT. IAM works as an irreversible alkylator by binding to the thiol group of the cysteine residues, thereby preventing the reduced disulfide from reforming. Alternatively, TCEP may be used in lieu of DTT, since it functions as both a reducing agent and an alkylating agent. TCEP also provides many advantages over DTT, such as being odorless and more stable at room temperature.[3,4]

This study examined the effect of IAM and TCEP on the quantity and quality of DNA extracted from hair, calcified tissue, semen, and blood. The following conditions were compared: (1) DTT alone (Standard Operating Protocol (SOP)); (2) DTT followed by IAM alkylation; (3) TCEP; and, (4) TCEP followed by IAM. DNA yields were assessed using nuclear and mitochondrial DNA (mtDNA) -specific quantitative Polymerase Chain Reaction (qPCR) methods and DNA quality was assessed following 16-locus Short Tandem Repeat (STR) analysis.

Both IAM and TCEP are water-soluble and were easily incorporated into a semi-automated SOP. Briefly, the SOP entails lysis of a specimen in buffer G2 from QIAGEN®, proteinase K, and DTT followed by purification on QIAGEN's® EZ1 platform. TCEP treatment simply involved replacement of DTT during the lysis step, at a concentration of 30mM with no further change in the lysis conditions. IAM treatment involved a separate incubation step with 150mM at 22°C for 30 minutes in the dark following the lysis step which included *either* DTT *or* TCEP.

The results revealed that for blood, TCEP treatment significantly increased DNA yield over the SOP by an average of 270%, whereas for semen, TCEP/IAM treatment increased yield over the SOP by an average of 350%. The results also confirmed that TCEP and IAM did not interfere with downstream STR analysis. The benefits of IAM and TCEP were similarly observed for calcified tissue and shed hair. Optimization experiments revealed that TCEP was optimal at 30mM.

In conclusion, the use of IAM, an alternative reducing agent, and TCEP, a reducing/alkylating agent, enhances DNA recovery from hair, calcified tissue, semen, and blood, thus promoting their successful forensic analyses. These enhancements should be particularly valuable for those challenging specimens which contain low copy DNA and/or degraded DNA.

DNA Extraction, Tris(2-carboxyethyl)phosphine, Iodoacetamide (IAM)

B115 The New Kit on the Block: Optimization of the QIAGEN® Investigator® 24plex GO! Kit for Direct Amplification

Daniel Watsula, MS, 10430 Furnace Road, Ste 107, Lorton, VA 22079; Jon Davoren, MS, 10430 Furance Road, Ste 107, Lorton, VA 22079; and Jangbir Sangha, MA, 10430 Furnace Road, Ste 107, Lorton, VA 22079*

After attending this presentation, attendees will understand how to achieve a high first-pass success rate when performing direct amplification of 1.2mm punches from buccal samples collected on non-treated paper with the QIAGEN® Investigator® 24plex GO! Kit. Attendees will also understand that a high first-pass success rate is achievable with reduced reaction volumes in addition to the standard manufacturer's protocol.

This presentation will impact the forensic science community by demonstrating the feasibility of direct amplification with the QIAGEN® Investigator® 24plex GO! Kit for the processing of reference samples collected on non-treated matrices. Attendees will also be presented kit characteristic data including average peak heights and inter- and intra-color balance values.

Recent trends in sample processing for databasing and paternity purposes have moved toward direct amplification systems. DNA samples can be collected and stored on non-treated matrices, such as the Bode Buccal DNA Collector™ until sample testing is required. QIAGEN's® recently released direct amplification kit encompasses the Combined DNA Index System (CODIS) core loci, the European standard set markers, and additional loci including a Y-chromosomal Short Tandem Repeat (Y-STR) and quality sensors.

This presentation will describe the studies performed with the Investigator® 24plex GO! Kit to obtain optimal results from samples collected utilizing the Bode Buccal DNA Collector™, a non-treated matrix, at varying reaction volumes: 20µl (Full Reaction), 10µl (Half Reaction), and 5µl (Quarter Reaction). A total of 100 (*n*=100) self-collected samples, approximately 1.5 years old at the time of testing, were utilized in this experiment. These 100 samples were stored in a controlled micro environment (~20°C-25°C and <10% humidity). Slightly aged samples were chosen as they may be more representative of a routine databasing sample rather than a fresh sample collected a few days prior to testing.

This presentation will display the optimized procedures for cell lysis, reaction mix components, thermal cycling parameters, and 3500xL injection conditions. The manufacturer's recommended procedure for "other papers" or non-treated matrices did not include a cell lysis step. The use of this procedure resulted in a poor success rate with very few samples exhibiting called alleles. A modified procedure was developed in order to perform a direct amplification procedure with a 1.2mm punch from a non-treated matrix. 2µl of QIAGEN's® Investigator® STR GO! Lysis Buffer (designed for a swab protocol) was added to a 1.2mm punch contained in a 96-well reaction plate. After ensuring that the punch was submerged in the liquid, the reaction plate was placed on a heat block set at 95°C for five minutes in order to dry the punch. Failure to incubate the sample and dry the punch resulted in DNA profiles with a ski slope, and the complete dropout of the "S" internal quality sensor indicating inhibition.

The volumes of the amplification reaction mix components followed the manufacturer's recommendations for the full (20µl 27 cycles) reaction. Each component was proportionally reduced to create the half (10µl 26 cycles) and quarter (5µl 25 cycles) reaction mixes.

Capillary electrophoresis setup and run parameters were optimized to achieve consistent, reliable, and reproducible results. The manufacturer's recommendation indicated to add 12µl of formamide/Internal Lane Standard (ILS) mix containing 12µl of formamide and 0.5µl of BTO550 ILS per sample. This resulted in low overall ILS peak heights (~300-500 Relative Fluorescence Units (RFUs)). Multiple samples failed as relatively low pull-up peaks (~100-200 RFUs) caused significant sizing issues resulting in uninterpretable data. Optimization parameters, including the use of additional ILS and a standard amplification product dilution, will be discussed during the presentation.

These optimized procedures resulted in a first pass success rate of 93% for a full reaction (20µl). The highest first pass success rate (99%) was observed when utilizing the half reaction (10µl) protocol. In the full reaction, the "S" quality sensor displayed RFU values, on average, slightly higher than the "Q" quality sensor. In the half reaction, the opposite was observed.

Direct amplification of reference samples utilizing QIAGEN's® Investigator® 24plex GO! Kit can provide a time-efficient method for obtaining complete genetic profiles with a high first pass success rate. This presentation will demonstrate methods to increase direct amplification feasibility by decreasing overall costs per sample through the use of reduced volume reactions.

Direct Amplification, QIAGEN®, Buccal Sample

B116 Increasing DNA Mixture Analysis Quality and Efficiency

George R. Riley, PhD, National Center Biotechnology Information, National Institutes of Health, 45 Center Drive, Bethesda, MD 20892; Robert M. Goor, PhD, Natl Ctr Biotechnology Information, National Institutes of Health, 45 Center Drive, Bethesda, MD 20892; Douglas Hoffman, MS, Natl Ctr Biotechnology Information, National Institutes of Health, 45 Center Drive, Bethesda, MD 20892; and Stephen Sherry, PhD, 45 Center Drive, Bethesda, MD 20892-6513*

After attending this presentation, attendees will better understand the challenges of distinguishing low-level artifacts from low-level alleles and how expert software can help distinguish between them to increase analyst efficiency and mixture profile interpretation reproducibility.

This presentation will impact the forensic science community by increasing awareness of how free, open-source software can be used to improve the significant problem of reproducibility in the interpretation of mixed DNA profiles.

Forensic DNA laboratories are attempting to find analytical thresholds that utilize the greatest amount of information possible in their Short Tandem Repeat (STR) mixture profiles without mistaking small artifacts and noise for alleles. Simultaneously, backlogs create pressure to use analyst time efficiently, while increased sensitivity increases the need for more reproducible interpretation.[1] The Scientific Working Group on DNA Analysis Methods (SWGDAM) Interpretation Guidelines for autosomal STR typing indicate that laboratories should not use their analytical threshold to avoid artifacts, but rather should apply analytical thresholds that take the laboratory's empirical noise levels into account. This allows laboratories to utilize the maximum information in STR profiles, and not "leave data on the table." As laboratories begin to use analytical thresholds below 30 Relative Fluorescence Units (RFU) to analyze complex mixed profiles, it becomes critical to be able to distinguish actual alleles from small STR artifacts and excursions in the baseline noise. STR analysis noise arises from Polymerase Chain Reaction (PCR) amplification artifacts and noise in the capillary electrophoresis analyzer. With more sensitive analytical thresholds, analysts spend more time determining whether low-level peaks in mixtures are alleles or artifacts. Software can employ various mathematically determined metrics to identify and discriminate low-level artifacts from alleles.

The Open Source Independent Review and Interpretation System (OSIRIS), downloadable from the National Center for Biotechnology Information (NCBI) OSIRIS homepage, was created in response to recommendations arising from the World Trade Center victim identification effort. OSIRIS is in use as an expert system for Combined DNA Index System (CODIS) samples and in clinical and forensic caseworking laboratories to analyze complex and low-level mixtures. OSRIS implements unique STR analysis metrics and a variety of artifact signatures that give the software exceptional capabilities when analyzing low-level STR profiles.

OSIRIS computes novel metrics for peak shape, peak shifting, sample-to-ladder fit, and channel-specific baseline noise. OSIRIS also matches various mathematical artifact signatures to different peak shapes and applies these metrics and signatures to discriminate allele peaks from artifacts and noise. Low-level artifacts include pull-up, non-specific peaks and random deviations in baseline noise that can appear to be alleles. Low-level alleles include those masked as shoulders on larger alleles and can be mistaken for artifacts or noise. Low-level artifact peaks can be difficult to visually distinguish from allele peaks. OSIRIS uses its calculated metrics, peak signatures, and its expert knowledge base to automatically identify and annotate these and other artifacts, saving significant analyst time and enhancing reproducibility among analysts.

Accurately and robustly identifying these artifacts increases the assurance of quality profiles and reduces both the editing burden and the number of conflicting analyst/reviewer calls that require resolution. In this way, OSIRIS improves the efficiency of analysts that are interpreting profiles. This gives analysts more time to do the important work of case interpretation.

DNA, Mixture, Reproducibility

B117 Using Bayesian Networks for the Interpretation of Low-Template DNA Profiles at the Activity Level

Ka-Man Pun, Polizia Cantonale - Scientifica, via Chicherio 20, Bellinzona, Ticino 6500, SWITZERLAND; and Christophe Champod, PhD, Batochime, Lausanne 1015, SWITZERLAND*

After attending this presentation, attendees will understand how to interpret low-template DNA profiles at the activity level using a graphical model and understand more about phenomena like transfer, background, persistence, and contamination.

This presentation will impact the forensic science community by changing the interpretative approach about DNA evidence generally based on source level propositions.

Today, a very limited quantity of epithelial cells deposited on an object can yield to a DNA profile. Such profiles are known under the term low-template DNA. Such sensitivity has opened new interpretative issues, principally because of the uncertainties regarding the nature of the biological material involved, the relevancy of the evidentiary material, and the representativeness of the DNA profile obtained. Interpreting DNA evidence arising from low-template DNA is a challenge yet to be solved. Significant contributions have been made when the case is assessed at the "source" level. Some researchers have started to investigate some of the factors that impact the trace level deposition and the profile quality. It is fair to say that very little is known about combining these variables into a coherent interpretative model and moving the interpretation of these cases from the "source" level to the "activity" level; however, "activity" level propositions should be presented in order to help the court understand the significance of the forensic findings within the context of a criminal case.

When considered in this context, the likelihood ratio reflects more than the mere discriminatory power of the DNA. The likelihood ratio also depends on different phenomena: transfer, persistence, contamination, and background. Each of these is influenced by the others. For example, the transfer phenomenon can be affected by the shedder's quality, the substrate's quality, and the nature of the contact; on the other hand, the persistence is dictated by the substrate quality, exogenous factors (i.e., temperature, humidity rate, light exposure, etc.), and the time between the evidence deposition and collection.

The purpose of this doctoral research is to design a graphical model (in the form of Bayesian networks) for solving the probabilistic relationships between parameters that are of relevance to the interpretation of a low-template DNA recovered during a police investigation. The model allows identifying the datasets that are the most relevant to the task at hand. By doing this, it is possible to focus the experimental data-gathering process only on the factors that play a major role. Then the model (appropriately informed with acquired data) allows an assignment of likelihood ratios at an activity level in a range of scenarios. In the end, a sensitivity analysis shows the robustness of the proposed model even in the presence of uncertainty in this forensic field.

Vehicle thefts have been selected from among the various forensic scenarios. This scenario presents several advantages compared with the others. First, different types of substrate are present in a car; second, the presence of the victim (the car owner) can be assumed/integrated into the graphical model.

According to the results, the factors having the strongest impact on the likelihood ratio are transfer and the background. These phenomena can also significantly affect the evaluation according to case-specific propositions.

Interpretation, DNA Evidence, Bayesian Networks

B118 2016 Update From the Scientific Working Group for the Analysis of Seized Drugs (SWGDRUG)

Sandra E. Rodriguez-Cruz, PhD, Drug Enforcement Admin, Southwest Laboratory, 2815 Scott Street, Vista, CA 92081*

After attending this presentation, attendees will better understand the latest documents and resources developed by SWGDRUG.

This presentation will impact the forensic science community by informing attendees of current activities, including revisions to the SWGDRUG recommendations, development of new Supplemental Documents, and other resources available to the seized-drug community.

SWGDRUG was formed in 1997 in a joint effort between the United States Drug Enforcement Administration (DEA) Office of Forensic Sciences and the Office of National Drug Control Policy (ONDCP). SWGDRUG works to improve the quality of the forensic examination of seized drugs and to respond to the needs of the forensic community by supporting the development of internationally accepted minimum standards, identifying best practices within the international community, and providing resources to help laboratories meet these standards.

During the summer of 2015, the SWGDRUG core committee started revising Part IIIB and Part IVB of the SWGDRUG Recommendations. These sections pertain to the categorization of analytical techniques and the validation of analytical methods, respectively. The development of new instrumental technologies and their introduction to seized-drug laboratories have brought up the need to clarify the categorization of techniques into A, B, or C groups. Revisions to SWGDRUG Recommendations Part IIIB will not involve changes in these categories, but will focus on providing guidance regarding the different modes of operation and variations within a technique and how their categorization could be affected.

Revisions to Part IVB incorporate clarifications on the performance characteristics that should be evaluated during the validation of qualitative and quantitative methods. Also, examples of method validation schemes for routinely used techniques such as color test, Gas Chromatography/Mass Spectrometry (GC/MS), and Infrared (IR) spectroscopy will also be included and made available to users in the form of a supplemental document.

SWGDRUG committee members are also in the process of developing Supplemental Document 6 (SD-6) titled "Examples of Measurement Uncertainty for Net Weight and Count Extrapolations." This document will assist seized-drug analysts by providing step-by-step examples for estimating uncertainty for scenarios where the net weight of an exhibit is obtained via extrapolation or when the total count of a dosage unit exhibit needs to be extrapolated.

This presentation will also summarize recent updates on some of the resources provided by SWGDRUG such as the MS library, the IR library, and the Drug Monographs. Laboratory analysts throughout the world can download the libraries from the SWGDRUG website and onto their laboratory instruments. Currently, the MS library contains more than 2,200 spectra, including many of the recently encountered synthetic cannabinoids, bath salt compounds, and their isomers. The IR library contains more than 150 reference materials which have been structurally characterized by the DEA Special Testing and Research Laboratory. More than 260 Drug Monographs are also available for use during reference material verifications.

The SWGDRUG core committee is comprised of representatives from federal, state, and local law enforcement agencies in the United States, Canada, Brazil, Great Britain, Germany, Austria, Switzerland, Australia, and Singapore. The following forensic organizations are represented: the European Network of Forensic Science Institutes (ENFSI), the Academia Iberoamericana de Criminalistica y Estudios Forenses (AICEF), the Asian Forensic Science Network (AFSN), and the United Nations Office on Drugs and Crime (UNODC). Core committee members also include forensic science educators and representatives from forensic science organizations across the United States, the American Society of Crime Laboratory Directors (ASCLD), the American Society for Testing and Materials (ASTM), and the National Institute of Standards and Technology (NIST).

Criminalistics, SWGDRUG, Seized Drugs

B119 Analysis and Extraction of Fentanyl in Seized Heroin Samples

Charles A. Richardson-Gongora, 19360 NW 10th Street, Pembroke Pines, FL 33029; Michael M. Healy, MBA, Manatee County Sheriff's Office, 600 301 Boulevard, W, Ste 202, Bradenton, FL 34205-7953; and Gerald Mattson, PhD, University of Central Florida Chemistry Department, 4000 Central Florida Boulevard, Orlando, FL 32816*

The goal of this presentation is to create an extraction procedure which can isolate fentanyl and identify compounds from heroin samples.

This presentation will impact the forensic science community by presenting a proposed extraction procedure that will assist in the determination of various fentanyl compounds present in heroin samples; this will prove helpful as fentanyl-laced heroin samples are being encountered with higher frequency.

The availability and demand of heroin has increased in the United States due to abusers switching from controlled prescription drugs to heroin.[1] Many factors may have contributed to this such as heroin's affordability, higher potency, and availability. These circumstances can lead to greater predicaments when individuals desire a stronger euphoria, thereby creating a demand for adding designer drugs to heroin. Though fentanyl is a Schedule II controlled substance, its readily synthesizable analogues are either Schedule I or not scheduled at all. As a result, issues in laboratory analyses can arise from similarities found in mass spectra and the lack and/or differing of scheduling pertaining to some analogues. Some consider fentanyl a "designer drug," regardless of its prevalence in medical practice. According to the Drug Enforcement Agency, some analogues may be considered as "controlled substance analogs"; however, "any substance…not intended for human consumption…" is considered an "exemption," allowing them to circumvent the law.[2]

This study is a response to an increase of fentanyl analogues (fentanyl-types) in seized heroin samples appearing in Manatee County, FL. Within the past two years, Manatee County has experienced an increase in heroin usage.[3] The two most encountered fentanyl-types were discovered to be acetylfentanyl and β-hydroxythiofentanyl. Acetylfentanyl, a known impurity of fentanyl synthesis, was normally found accompanied by fentanyl.[4] Currently, it is being considered for temporary scheduling by the Department of Justice as a Schedule II designer drug. The other analogue, β-hydroxythiofentanyl, was seen often accompanied by dimenhydrinate (Dramamine®) or cetirizine, possibly to counteract undesired effects and to lower fentanyl potency. The presence of β-hydroxythiofentanyl is of concern because of its lack of scheduling in the state of Florida and similar mass spectrum to fentanyl.

β-hydroxythiofentanyl produces a similar mass spectrum to fentanyl and therefore needs additional confirmation such as retention-time comparison. The identification of acetylfentanyl can be difficult owing to similarities to acetylfentanyl-4-methylphenethy; however, a standard was not procured and no retention time comparisons could be made. Instead, Attenuated Total Reflectance/Infrared (ATR/IR) spectrophotometry was conducted on extracts of confirmed heroin samples containing fentanyl-types. Extractions were conducted using a liquid extraction method based upon fentanyl and heroin solubility and an online purification method.

The extracts were analyzed first using Gas Chromatography coupled with Mass Spectrometry (GC/MS) to confirm the success of an extraction and then using ATR/IR spectroscopy to determine final composition of the compound. The method was successful in isolating the fentanyls; however, extractions were unable to separate fentanyl-types from each other or other cutting agents. The concomitants did not pose any issues due to lower concentrations than the target analogue. The analysis of five extracts and 406 chromatographs of seized heroin samples qualitatively confirmed that the main analogues present in Manatee County were acetylfentanyl and β-hydroxythiofentanyl in lieu of other analogues

Fentanyl, Fentyl Analogues, Heroin

B120 Analysis of Prescription Drugs With Abuse-Deterrent Properties

Robert P. Bianchi, BS, 12728 Penguin Drive, Bradenton, FL 34212*

After attending this presentation, attendees will better understand the analysis of drugs with abuse-deterrent properties.

This presentation will impact the forensic science community by improving the efficiency of controlled drug analysis.

Prescription drug abuse is sweeping the nation faster than ever before. In 2012, an estimated 2.4 million Americans used prescription drugs non-medically for the first time within the past year, which averages approximately 6,700 new users per day, according to the 2012 National Survey on Drug Use and Health.[1] Prescription drug abuse is the non-medical use of a medication without a prescription, in a way other than as prescribed, or for the experience or feelings elicited.

In 2013, an estimated 24.6 million or 9.4% of the American population aged 12 or older were currently illicit drug users. Marijuana remains the most commonly used illicit drug with 19.8 million users (more than heroin and cocaine combined). Non-medical use of prescription drugs is the second-largest category of abused drugs at 6.5 million users or 2.5% of the population. Centers for Disease Control and Prevention classified this phenomenon as an epidemic.

The classes of prescription drugs most commonly abused are: opioid pain relievers, such as Vicodin® or OxyContin®; stimulants for treating Attention Deficit Hyperactivity Disorder (ADHD), such as Adderall®, Concerta®, or Ritalin®; and Central Nervous System (CNS) depressants for relieving anxiety, such as Valium® or Xanax®.

The pharmaceutical industry and government agencies have embarked on an initiative to reduce prescription drug abuse by making the formulations more difficult to abuse. The advent of abuse-deterrent formulations is creating new challenges for the forensic community. Abuse-deterrent formulations of interest have in part been categorized by the Food and Drug Administration (FDA) as follows: (1) Physical/chemical barriers — Physical barriers can prevent chewing, crushing, cutting, grating, or grinding of the dosage form. Chemical barriers, such as gelling agents, can resist extraction of the opioid using common solvents like water, simulated biological media, alcohol, or other organic solvents. Physical and chemical barriers can limit drug release following mechanical manipulation or change the physical form of a drug, rendering it less amenable to abuse. (e.g., reformulated OxyContin®); (2) Agonist/antagonist combinations — An opioid antagonist can be added to interfere with, reduce, or defeat the euphoria associated with abuse. The antagonist can be sequestered and released only upon manipulation of the product; (3) Aversion — Substances can be added to the product to produce an unpleasant effect if the dosage form is manipulated or is used at a higher dosage than directed; and, (4) New molecular entities and prodrugs — The properties of a new molecular entity or prodrug could include the need for enzymatic activation, different receptor binding profiles, slower penetration into the central nervous system, or other novel effects.

These new formulations are designed to make extraction by abusers more difficult; however, they also make it more complicated for analysts in a laboratory. Forensic chemists have always been challenged by prescription drug exhibits and the advent of abuse-deterrent formulations makes analysis more difficult. Heroin, cocaine, and methamphetamine exhibits are routine and easier to characterize, while abuse-deterrent prescription drugs present unique challenges. The presence of certain ingredients will dictate how the analysis should be approached. For example, the presence of Polyethylene Oxide (POLYOX), which is used as a binding, thickening, or water-retention agent, will inhibit solvent extraction. Analysts should determine the ingredients contained in a prescription drug by visiting internet sites or published dosage form descriptions such as http://www.drugs.com/pill-logo-identification.html, http://www.rxlist.com/pill-identification-tool/article.htm, or the *Physician's Desk Reference*. Once the formulation is known, then the analytical approach can be developed. This is especially important if there is a legal requirement to report the amount of controlled substance present.

Abuse Deterrent, Prescription Drugs, Forensic Analysis

B121 The Prevalence of Promethazine Dimerization in Forensic Samples of "Purple Drank"

Tyler Williams, 98 Hearthstone Way, Hanover, MA 02339; James T. Miller, BS, Houston Forensic Science Center, 1200 Traves, 20th Fl, Houston, TX 77002; and Glen P. Jackson, PhD, West Virginia University, Dept of Forensic and Investigative Science, 208 Oglebay Hall, Morgantown, WV 26506-6121*

After attending this presentation, attendees will understand how exposure to Ultraviolet (UV) light can cause the formation of a promethazine dimer.

This presentation will impact the forensic science community by providing an explanation for the presence of additional chromatographic peaks with promethazine-like mass spectra in seized samples containing promethazine.

In certain parts of the country, codeine cough syrups are consumed as a recreational drug known as "purple drank." One of the other main components in this cough syrup is an antihistamine and antiemetic drug called promethazine. When "purple drank" beverages are collected and analyzed by forensic laboratories, they often find two or more chromatographic peaks with indistinguishable promethazine-like Electron Ionization (EI) mass spectra. One of these peaks has a Gas Chromatography (GC) retention time equal to standard promethazine, whereas a second GC peak can elute more than a minute later, with an indistinguishable mass spectrum. This study was conducted to help identify the cause and identity of the second mystery peak.

Samples of promethazine were dissolved in chloroform at 50ppm and analyzed via Gas Chromatography/Mass Spectrometry (GC/MS) to determine the origin of the second peak. Initial experiments replicated the Standard Operating Procedure (SOP) of an American National Standards Institute-American Society of Quality (ANSI-ASQ) National Accreditation Board/ Forensic Quality Services (ANAB/FQS) -accredited crime laboratory for the extraction and GC/MS analysis of aqueous samples suspected to contain promethazine and codeine. Standard promethazine was dissolved in water to simulate the cough syrup, and aliquots were made basic using sodium hydroxide or a saturated sodium carbonate solution and extracted into chloroform. Neither of these caused the appearance of the second peak. The samples were also made acidic using hydrochloric acid and extracted into chloroform, but these results did not show any additional peaks besides the normal promethazine peak.

The core/base structure of promethazine is phenothiazine, and it has been found to form radicals when exposed to UV light. For this reason, the possibility of UV-induced chemistry of this phenothiazine derivative was explored. Samples of promethazine were dissolved in chloroform and were left under long-wave or short-wave UV light for different times. Upon examination using the GC/MS, the long-wave UV exposure for two or four hours showed no additional peaks, but the sample exposed to short-wave UV for four hours showed a new small GC peak more than a minute later than the promethazine peak, which was also readily abundant. Additional studies were then conducted to determine the cause of the "new" peak. One aliquot of dissolved promethazine was placed on a windowsill for two days, one was placed under short-wave UV light for seven hours, one was placed on a desktop (away from an outside window) for two days, and one was placed in the dark for two days. The samples in the dark and on the desk showed no sign of the second peak. The sample left on the windowsill and the sample left under short-wave UV light for seven hours showed that more than 50% of the promethazine had either oxidized or converted to the dimer form. Additional Nuclear Magnetic Resonance (NMR) studies were also conducted to confirm the dimerization product.

In conclusion, this study provides evidence that upon exposure to UV light, promethazine will form degradation products, which include a dimerized form of the drug. This additional peak could presumably be avoided by storing casework in amber vials or otherwise limiting the exposure to UV radiation.

Drug Chemistry, Gas Chromatography, Promethazine

B122 Adulteration of Psychoactive Herbal Supplements Revealed by Direct Analysis in Real-Time Mass Spectrometry (DART®-MS)

Ashton D. Lesiak, University of New York at Albany, Dept of Chemistry, 1400 Washington Avenue, Albany, NY 12222; Robert B. Cody, PhD, JEOL USA, Inc, 11 Dearborn Road, Peabody, MA 01960; Masaaki Ubukata, PhD, JEOL USA, Inc, 11 Dearborn Road, Peabody, MA 01960; and Rabi A. Musah, PhD, State University of New York at Albany, Dept of Chemistry, 1400 Washington Avenue, Albany, NY 12222*

After attending this presentation, attendees will understand the value of Direct Analysis in Real-Time Mass Spectrometry High Resolution Mass Spectrometry (DART®-HRMS) for rapid confirmation of the identity of psychotropic plant material and for screening psychoactive herbal supplements for banned substances.

This presentation will impact the forensic science community by demonstrating the benefit of DART®-HRMS in drug chemical analysis, especially in terms of the speed and simplicity of analysis of samples in complex matrices. Definitive identification of psychoactive compounds can be accomplished using in-source Collision-Induced Dissociation (CID) and screening for adulterants can be rapidly performed. The ability to characterize and identify not only unscheduled plant-based psychotropics but also controlled substances could assist in reducing casework backlogs in forensic drug laboratories.

Sceletium tortuosum, commonly known as Kanna, is a psychotropic plant that has been identified by the United Nations Office on Drugs and Crime as a drug of concern.[1,2] Historically used for medicinal purposes, Kanna is marketed as an antidepressant, stimulant, and a natural alternative to traditional drugs of abuse.[2,3] Kanna is often sold as an herbal supplement and is found in multiple incarnations (seeds, powders, resin, etc.), which makes it challenging to identify. Because of its classification as a dietary or herbal supplement, Kanna is exempted from mandatory regulation and testing by the United States Food and Drug Administration (FDA). Consequently there is little oversight regarding the ingredient profile of Kanna products.

There have been many reported cases of herbal supplements being laced with toxic or banned substances.[4-6] The sample matrices are often complex, which makes analysis and definitive identification of these substances using conventional methods quite challenging. Hyphenated methods such as Gas Chromatography/Mass Spectrometry (GC/MS) and Liquid Chromatography/Mass Spectrometry (LC/MS) can be used to determine supplement identity and reveal the presence of adulterants; however, these approaches often require tailored method development that targets specific analytes of interest. With the increasing numbers of psychoactive herbal supplements on the market, it is impractical to develop standard operating protocols for each of these unscheduled substances.

DART®-HRMS is an ambient ionization method that can circumvent some of the aforementioned challenges in plant-based sample analysis. DART®-HRMS screening of Kanna samples revealed that these herbal products exhibit characteristic chemical fingerprints that are consistent with the presence of psychoactive and chemotaxonomic markers previously detected in the *S. tortuosum* species. These include mesembrine, mesembrenol, mesembrenone, and hordenine. Comparison of the in-source CID spectra of available authentic standards to in-source CID spectra of the Kanna products confirmed the presence and identity of the biomarker hordenine. Furthermore, the results of the in-source CID analysis revealed the presence of ephedrine in one of the herbal supplements. This finding was independently confirmed by GC/HRMS analysis.

The identification of ephedrine as an adulterant in Kanna products demonstrates the benefit of using DART®-HRMS for screening of psychoactive plant material and herbal supplements, as many traditional analysis methods would have been unlikely to have revealed its presence. DART®-HRMS was shown to be a powerful tool to not only screen plant-based drugs of abuse for psychotropic alkaloids, but also to reveal the presence of banned substances and adulterants.

B123 Toward On-Site, Real-Time, Confirmatory Analysis of Drugs and Their Optical Isomers Using a Battery-Operated, Portable, Ultra-Fast Capillary Electrophoresis/Mass Spectrometry (UFCE/MS)

Mehdi Moini, PhD, George Washington University, Dept of Forensic Sciences, 2100 Foxhall Road, NW, Washington, DC 20007; and Christopher M. Rollman, BS, George Washington University, 2100 Foxhall Road, NW, Somers Hall, L14, Washington, DC 20007*

After attending this presentation, attendees will better understand a novel portable device for on-site, real-time confirmatory analysis of drugs and their optical isomers.

This presentation will impact the forensic science community by discussing the role of a portable confirmatory technique for the detection of explosives, illicit drugs, and their optical isomer that takes approximately one minute.

In the past several years, there has been considerable interest in developing hand-held devices for detection of chemicals and biological samples in the forensics area. Most of the devices are based on spectroscopic techniques and are therefore only sufficient for screening purposes. To address the need for portable confirmatory methods, a variety of portable mass spectrometers have been developed and used with real-time ionization techniques such as Desorption Electrospray Ionization (DESI), Direct Analysis In Real Time (DART®), and paperspray ionization. The limited or lack of separation with these ionization techniques makes the analysis of complex mixtures difficult; therefore, a portable and fast separation technique is desired. A variety of fast separation techniques based on Gas Chromatography (GC), Liquid Chromatography (LC), supercritical fluid chromatography, and Capillary Electrophoresis (CE) have been developed, but CE is the most amenable to miniaturization. Presented here is a portable (battery-operated), UFCE/MS for fast separation of drugs and their optical isomers.

Analyses were performed using fused silica capillaries utilizing a porous tip to interface between the CE and MS. Short (≤25cm long) capillaries with inner diameters between 5µm and 15µm were used for separation. The capillary wall was coated using polybrene, which under reverse polarity mode provided electro-osmotic flow toward the outlet. A separation voltage of -25kV was used to achieve ≥1,000V/cm across the capillary. A background electrolyte analyses of (+)-(18-crown-6)-2,3,11,12-tetracarboxylic acid (18-C-6-TCA) was used.

The portable UFCE electrospray ionization source fits in front of a low- or high-resolution MS similar to a conventional electrospray/nanospray ionization source and has about the same size and weight. The UFCE ionization source is equipped with two high-voltage power supplies (±25kV HVPS) capable of operating in forward or reverse polarity modes and powered by a 12V rechargeable Lithium ion battery, making it compatible with a portable MS. The device was able to separate illicit drugs (including amphetamines, cathinones, and cannabinoids) and their optical isomers in approximately one to two minutes. The portable ultrafast CE ionization source for MS allows for separation of compounds and their isomers in about one minute.

Portable CE, CE/MS, Explosive Drugs Optical Isomer

B124 Single Crystal X-Ray Diffraction in Forensic Drug Analysis

Matthew R. Wood, MS, Ocean County Sheriff's Dept, Forensic Science Laboratory, Toms River, NJ 08753; Thomas A. Brettell, PhD, Cedar Crest College, 100 College Drive, Allentown, PA 18104; Ivan Bernal, PhD, Rutgers University - Newark, 73 Warren Street, Newark, NJ 07102; Hugh W. Thompson, PhD, Rutgers University - Newark, 73 Warren Street, Newark, NJ 07102; and Roger A. Lalancette, PhD, Rutgers University - Newark, 73 Warren Street, Newark, NJ 07102*

After attending this presentation, attendees will better understand the crystal structure of the precipitate resulting from the gold chloride microcrystal test with ecgonine, several phenethylamines, and 3,4-methylenedioxypyrovalerone (MDPV). Additionally, attendees will understand the crystal structure of several cathinones ("bath salts") and the additional information that X-ray diffraction can provide to the analyst. This presentation will describe how these structures were determined using single crystal X-ray diffraction techniques and the potential implications for the microcrystal testing of other drugs.

This presentation will impact the forensic science community by providing essential information regarding the molecular structure and interactions within the crystal lattice of the compounds investigated as well as the benefits of single crystal X-ray structure determination.

The analysis of controlled dangerous substances by microcrystal tests has been largely empirical, relying on the experience and training of the analyst to make conclusions regarding the identity of microcrystalline precipitates viewed microscopically. The microscopist had little support beyond the optical characteristics provided by the polarized light microscope to base his/her conclusions. While the morphology and optical properties of the resulting crystals have been studied and documented, very little structural information has been available on the molecular level. Single crystal X-ray diffraction is an ideal technique for determining the chemical composition of crystals containing highly diffractive heavy metals, such as gold chloride complexes.[1]

Ecgonine precipitates as crystals with the gold chloride reagent as both the anhydrous salt and the hydrate. Single crystals of ecgonine-gold chloride was grown for comparison to previous work with cocaine-gold chloride.[2] For the hydrate, the asymmetric unit consists of four protonated cations of ecgonine, surrounded by five gold chloride anions and seven waters, one of which is a hydronium ion for charge balance. The crystal lattice contains a network of water molecules woven between the cations and anions making hydrogen bonds with the hydroxyl and carboxyl functions of the ecgonine molecules. The anhydrous crystal of the ecgonine salt demonstrates close contact bonding between the gold chloride anions and the ecgonine cations and an intramolecular hydrogen bond between the protonated nitrogen and the carboxyl oxygen.

A series of related phenethylamines (ephedrine, amphetamine, and methamphetamine) were grown with gold chloride as single crystals for X-ray diffraction. Both ephedrine and methamphetamine precipitated as salts with the 1:1 ratio of cation-to-anion as seen with other microcrystal tests. The ephedrine-gold chloride complex shows a stratified internal arrangement in which the phenyl rings of the ephedrine cations are in bands every one-third of the unit cell and the gold chloride anions reside in clusters near the protonated N atoms of the cations.

However, amphetamine produced a unique cycloaurate complex with a centrally located Au atom bound bidentate to the amphetamine ligand and to two Cl atoms. In the methamphetamine-gold chloride crystal structure, the gold chloride anion is aligned between the phenyl rings of the cations, deviating from a line drawn between the centroids of the phenyl rings by less than 0.6Å.

The "bath salt" MDPV was studied as the gold chloride precipitate. A single hydrogen bond exists from the protonated N atom of the cation to the proximal anion. Additionally, several law enforcement seizures of crystal MDPV were examined directly by X-ray crystallography as submitted to the laboratory. The analysis of these samples has provided some insight into the nature of these dangerous compounds.

The purpose of this research is to gain an understanding of how the structure of the selected compounds and their gold (III) chloride complexes may play a role in the formation of crystals visualized by the traditional microcrystal test. This is an ongoing research project at Rutgers University. Further crystallographic studies will focus on other related drug compounds and additional microcrystal tests.

Drug Analysis, Crystallography, Microcrystal Tests

B125 Microcrystalline Tests in Conjunction With Vibrational Spectroscopy for the Analysis of Illicit Drugs and Their Metabolites

Brooke W. Kammrath, PhD, University of New Haven, Forensic Science Dept, 300 Boston Post Road, West Haven, CT 06516; Shannon Tilly, 41 William Street, Fair Haven, NJ 07704; Kara Kovacev, 53 Riverbank Road, Saugus, MA 01906; Natasha L. Kuegler, BS, University of New Haven, Forensic Science Dept, 300 Boston Post Road, West Haven, CT 06516; Pauline E. Leary, PhD, Smiths Detection, 1934 Bulls Head Road, Stanfordville, NY 12581; and John A. Reffner, PhD, John Jay College of Criminal Justice, 524 W 59th Street, New York, NY 10019*

After attending this presentation, attendees will understand that the coupling of microcrystalline tests with vibrational spectroscopy (either infrared or Raman) is an excellent analytical scheme for drug identification because it is rapid, reliable, and creates a reviewable record of the analysis.

This presentation will impact the forensic science community by presenting a method of drug analysis that pairs microcrystalline tests with vibrational spectroscopy, thus creating an analytical scheme that satisfies the Scientific Working Group for the Analysis of Seized Drugs (SWGDRUG) standards and can be easily incorporated into a criminalist's drug-testing protocol.

The analysis and identification of illicit drugs is a critical component of the field of forensic science as it constitutes a majority of casework performed in most forensic laboratories. Any analytical method for the identification of drugs must be rapid, reliable, and create a reviewable record in order to satisfy legal standards as well as manage the large number of submissions to a forensic laboratory. SWGDRUG has established minimum standards for the forensic identification of illicit drugs.[1] The SWGDRUG guidelines classify techniques into three categories which are based on discriminating power, with A being the most and C the least. One proposed analytical scheme is using two techniques, one of which must be from category A (infrared spectroscopy, Raman spectroscopy, mass spectrometry, nuclear magnetic resonance spectrometry, or X-ray diffractometry). This research proposed the coupling of microcrystalline tests (a Category B technique) with vibrational spectroscopy (either infrared or Raman) as a fast, efficient, inexpensive, and non-destructive drug analysis and identification analytical scheme that satisfies SWGDRUG standards and can be easily executed by criminalists.

Microcrystalline tests are highly developed precipitation tests that use specific reagents to create crystals with particular morphologies that can be used to determine the presence of many chemicals, including both controlled substances and other related compounds. An advantage of microcrystalline testing is that there are a plethora of crystal habits that show morphological differences, and this enables closely related analogs to be readily differentiated. In addition, these tests work with sample mixtures and, in effect act, as a method of separation because the reagent will form characteristic microcrystals only with specific drugs. Although in the past microcrystalline tests were considered to be confirmatory techniques, today they are used as preliminary or presumptive testing methods to indicate what the drug might be, which is why instrumentation is needed to confirm the results. Infrared and Raman spectroscopy are common forms of instrumentation that are used in forensic laboratories to identify illicit drugs. Although both types of vibrational spectroscopy are considered to generate the highest discriminating capabilities, the discrimination power is considered to be diminished in mixtures because what is produced is a combined spectrum that is more difficult to interpret. Thus, a method of separation is often employed to make a pure sample capable of spectroscopic analysis.

The proposed method uses microcrystalline tests both to identify the drug by its morphology and also as a means for isolating the drug for vibrational microspectral analysis. Prior research published by Wielbo and Tebbett coupled infrared microspectroscopy with microcrystalline tests of seven drugs; however, the microcrystalline samples were allowed to dry at room temperature prior to being analyzed by infrared spectroscopy.[2] The current research improves on this method by using a diamond-Attenuated Total Reflection (d-ATR) infrared microprobe, thus enabling analysis of the microcrystals in solution.[3] Research presented at the 2007 American Academy of Forensic Sciences (AAFS) Annual Scientific Meeting by Cullinan and Bell used both Raman and infrared microspectroscopy to analyze drug microcrystals of phenylethylamines (amphetamine, methamphetamine, phentermine, and ephedrine).[4] This research has extended the application of this technique to the identification and confirmation of cocaine and its metabolite ecognine, morphine, codeine, as well as additional phenylethylamines, such as common bath salts (methylenedioxypyrovalerone or MDPV and ethylone) and 3-4-methylenedioxymethamphetamine (MDMA).

The coupling of microcrystalline tests with vibrational spectroscopy is a rapid testing method which requires minimal reagents, combines two reliable techniques, produces reviewable records of the results (in the form of photomicrographs and spectra), is non-destructive (test compounds are recoverable from the test slide), uses instrumentation that is currently available in most forensic laboratories, and satisfies SWGDRUG guidelines for the identification and confirmation of illicit drugs. This research demonstrated that pairing microcrystalline tests with either infrared or Raman microspectroscopy is a valuable technique for drug identification within the ever-growing field of forensic drug analysis.

Drugs, Microcrystalline Tests, Spectroscopy

B126 Using Climate Modeling to Predict the Origin of Seized Cannabis

Jurian A. Hoogewerff, PhD, National Centre for Forensic Studies, Faculty ESTeM, University of Canberra, Bruce - Canberra, ACT ACT 2601, AUSTRALIA; Shaerii Sarker, MSc, Department of Chemistry, University of Otago, Dunedin 9016, NEW ZEALAND; Alan Hayman, PhD, Department Chemistry, University of Otago, Dunedin 9016, NEW ZEALAND; and Russell Frew, PhD, Department Chemistry, University of Otago, Dunedin 9016, NEW ZEALAND*

After attending this presentation, attendees will appreciate the potential of using climate data to predict the isotopic composition of natural drugs and other natural materials and the use of their spatial distribution for geographical provenancing intelligence.

This presentation will impact the forensic science community by creating awareness that it is possible to use geospatial climatic data to obtain natural drugs' provenance intelligence.

The hydrogen and/or oxygen isotopic composition of many natural biological materials is strongly dependent on the local isotopic composition of groundwater, which in is turn directly related to that of local precipitation. The Hydrogen (H) and Oxygen (O) isotopic composition of precipitation is a function of a number of factors. The cause of different relative abundances of the H and O isotopes in water molecules is the isotopic fractionation during evaporation and condensation. As the contribution of the different masses of the isotopes on the total energy of the water molecule is temperature dependent and more pronounced at lower temperatures, also more fractionation is observed at lower temperatures.

The two main factors that determine the H and O isotopic composition of precipitation at a specific location are the isotopic composition of the surface water in the source region where evaporation took place (which for major air masses is often one of the oceans) and the temperature during precipitation. Both the temperature of the source surface water and that of the air mass during precipitation will correlate with the general geographical latitude where a specific air mass is travelling. As an air mass travels inland and loses moisture through precipitation, the isotopic composition of the residual air mass will be isotopically lighter as it loses the heavier fraction in the precipitation. Often as an air mass travels inland, its altitude will increase, especially over mountainous areas, and as temperature generally drops with altitude, the isotopic composition of the precipitate also changes.

As the mentioned processes are well understood and high-resolution climatic and topographic data are freely available, it is thus possible to create spatial models that predict the isotopic composition of groundwater that is taken up by plants such as cannabis. In order to develop the critical modeling step to link the isotopic composition of groundwater with that of cannabis buds and/or leaves, many samples of cannabis of different climate zones would be required for analysis. As the seizing of cannabis by the police in New Zealand is opportunistic and not in a systematic spatial or temporal manner, it was decided to test the use of blackberry as a proxy for cannabis. Blackberry belongs to the same botanical order of Rosales and is ubiquitous in New Zealand. Blackberry was collected at 130 locations on the North and South Islands. In addition, cannabis samples from four locations at different latitudes were collected by the Institute of Environmental Science and Research (ESR) and New Zealand police for comparison and validation with the blackberry results.

Monthly water isotope data collected from 50+ locations by this group from 2007 to 2010 was combined with climate data from the New Zealand climate research organization (Virtual Climate Station Network-NIWA) to produce a model that predicts the isotopic composition of precipitation on a 5km x 5km scale for the whole of New Zealand. Subsequently, the precipitation isotope data were combined with hydrogen isotope measurements of the collected blackberry leaves and a linear relation was observed. This linear relation in turn allowed for the creation of a prediction model of the H isotope composition in blackberry leaves anywhere in New Zealand.

To validate the use of the blackberry data as a proxy for cannabis, both bulk leaf and compound-specific measurements of the hydrogen isotopic composition of both plants were compared. The initial data shows linear correlations that provide proof of principle but a larger and controlled set of cannabis samples needs to be collected to validate the use of the prediction model throughout the whole of New Zealand. In this presentation, a source apportionment tool will be presented that depicts the statistically most likely source regions for future seized cannabis samples which will provide New Zealand with strategic intelligence as to where to direct resources to detect and destroy illegally grown cannabis.

Cannabis, Climate Modeling, Isotopes

B127 Applicability of Ultra High-Performance Supercritical Fluid Chromatography (UHPSFC) as a Separation Technique for Synthetic Cannabinoids and Synthetic Cathinones

Ira S. Lurie, PhD, George Washington University, Dept of Forensic Science, 2100 Foxhall Road, NW, Somers Hall, Lower Level, Washington, DC 20007; Stephanie R. Breitenbach, BS, 165 Cross Point Drive, Owings, MD 20736; Walter F. Rowe, PhD, George Washington University, Department of Forensic Science, 2100 Foxhall Road, NW, Washington, DC 20007; Mike Hitchcock, MS, U.S. Postal Inspection Service, Forensic Laboratory Services, 22433 Randolph Drive, Dulles, VA 20104-1000; Ioan Marginean, PhD, George Washington University, 2100 Foxhall Road, NW, Somers Hall L14C, Washington, DC 20007; Stacey L. Obrien, BS, QualX Corporation, 8300 Boone Boulevard, #500, Vienna, VA 22182; and Bruce R. McCord, PhD, Florida International University, Dept of Chemistry, University Park, Miami, FL 33199*

After attending this presentation, attendees will understand some separation principles of UHPSFC, in particular the applicability to the separation of synthetic cannabinoids and synthetic cathinones. Attendees will gain insight into whether UHPSFC should be used by forensic chemists in their general analysis scheme for emerging drugs.

This presentation will impact the forensic science community by presenting a technique that has the potential to be the best chromatographic method for distinguishing between very similar solutes, such as positional isomers and diastereomers. This information could be particularly valuable in aiding the analyst in determining which controlled substance is present and to distinguish between a controlled and non-controlled emerging drug.

The recently introduced separation technique UHPSFC produces highly efficient and rapid separations performed on a new generation of analytical SFC instruments with an environmentally friendly mobile phase, containing carbon dioxide as the major component. Supercritical and subcritical carbon dioxide has properties that are intermediate between a liquid and a gas, giving it excellent diffusivity while maintaining liquid-like properties. UHPSFC, similar to high-performance liquid chromatography and ultra high-performance liquid chromatography, is advantageous for drugs that are thermally labile, polar and non-volatile solutes that are problematic for Gas Chromatography (GC) analysis. UHPSFC offers increased selectivity for very similar compounds due to interactions with the stationary phase such as hydrogen bonding, dipole and pi-pi interactions, and is particularly useful for the separation of designer drugs including synthetic cannabinoids and synthetic cathinones ("bath salts").

The Scientific Working Group for the Analysis of Seized Drugs (SWGDRUG), which is responsible for setting standards for drug analysis, does not list SFC as an approved separation technique. In order to be listed for SWGDRUG under Category B, a separation technique should not only offer reasonable separation ability but be orthogonal to accepted techniques such as GC and Liquid Chromatography (LC).

In these studies, four achiral columns, including 2-PIC, Diol, DEA, and 1-AA (1.7µm 3.0 x 100m), and three chiral columns, including AM1, CEL1, and CEL2 (2.5µm 3.0 x 150mm), were investigated for the separation of synthetic cannabinoids and bath salts using carbon dioxide with various modifiers and additives. The modifiers included methanol, acetonitrile, ethanol, and isopropanol, while the additives included ammonium formate and ammonia. Detection was carried out by photo diode array-Ultraviolet (UV) in series with single quad Mass Spectrometry (MS). The synthetic cannabinoids studied consisted of 24 controlled drugs, including a pair of positional isomers and two pairs of diastereomers, nine non-controlled positional isomers of controlled JWH-018, a non-controlled positional isomer of controlled JWH-073, and a non-controlled diastereisomer of HU-210. The "bath salts" investigated included 15 controlled drugs, with three pairs of positional isomers, seven non-controlled positional isomers of controlled pentedrone and 4-methylcathinone, four non-controlled positional isomers of controlled mephedrone and buphedrone, three non-controlled positional isomers of controlled α-PVP, two non-controlled positional isomers of controlled 4-MEPP and α-PBP, and one non-controlled positional isomer of controlled methcathinone, butylone, methylone, pentylone, and MDPV.

Although significant co-elution was observed for the controlled synthetic cannabinoids using UHPSFC, the co-eluting compounds could easily be distinguished by MS detection. Furthermore, the work demonstrates that UHPSFC is particularly valuable for the separation of isomers (both controlled and non-controlled) and all the positional and most diastereomers of the synthetic cannabinoids were resolved using this group's optimized parameters in less than ten minutes. For the "bath salts," good overall resolution was obtained for all compounds including their positional isomers in less than eight minutes using optimized UHPSFC conditions. All of the controlled "bath salts" could be distinguished by a combination of retention time and MS detection.

Lastly, UHPSFC separations for the above emerging drugs were compared to separations obtained by both GC and Ultra High-Pressure Liquid Chromatography (UHPLC), with particular attention paid to the separation of positional isomers and diastereomers. The latter techniques can be particularly problematic for the separation of positional isomers.[1] The degree of orthogonality of UHPSFC, GC, and UHPLC was demonstrated for the separation of both synthetic cannabinoids and bath salts using principal component analysis.

This project was supported by the National Institute of Justice, Office of Justice Programs, and United States Department of Justice. The opinions, findings, and conclusions or recommendations expressed in this publication are those of the authors and do not necessarily reflect those of the Department of Justice.

Synthetic Cannabinoids, Synthetic Cathinones, Supercritical Fluid

B128 Identification of Regioisomers Via Gas Chromatography Coupled With Vapor-Phase Infrared Detection (GC-IRD)

Janice L. Aleman, BS, 510 Deerview Drive, Fredericksburg, TX 78624; Jesse M. Zavala, MS, Harris County Institute of Forensic Sciences, 1885 Old Spanish Trail, Houston, TX 77054; Kyle E. Vircks, MS, Harris County Institute of Forensic Sciences, 1885 Old Spanish Trail, Houston, TX 77054; and Warren C. Samms, PhD, 1885 Old Spanish Trail, Houston, TX 77054*

After attending this presentation, attendees will be informed about the utility of using GC-IRD to differentiate regioisomers of abused substances.

This presentation will impact the forensic science community by providing information about how to utilize GC-IRD to distinguish regioisomers that are often difficult to differentiate using common methodologies. Due to identical mass spectra and similar retention times, laboratories are often unable to distinguish regioisomeric groups. The ability to differentiate these isomers allows the forensic science community to unambiguously identify newly designed substances. This is especially important when one isomer is controlled but another is not.

Designer drugs are appearing at an alarming rate across the world, requiring forensic chemists to develop new techniques for analysis. In many jurisdictions, designer drugs circumvent existing laws and are sold online or in smoke shops. In a previous validation study, various isomer sets of designer phenethylamines and cathinones were investigated. During the validation process, a few compounds presented potential data quality issues, such as low reproducibility of IR spectra resulting in incorrect library matches. Four of these compounds were 2,3-dimethylmethcathinone (2,3-DMMC), 3,4-dimethylethcathinone (3,4-DMEC), 2-methylmethcathinone (2-MMC), and 3-methylmethcathinone (3-MMC). Interestingly, the standards 2,4-dimethylmethcathinone (2,4-DMMC) and 2,4-dimethylethcathinone (2,4-DMEC) did not present these issues during the initial study and data was satisfactorily acquired. In the present study, analytical standards of 2,3-DMMC, 3,4-DMEC, 2-MMC, and 3-MMC were studied along with 5-(2-aminopropyl) indole (5-IT), alpha-methyltryptamine (AMT), as well as others. Prior to this investigation, this drug chemistry laboratory was unable to confirm these substances because they could not be separately and unambiguously identified. This is problematic in Texas, and presumably other states, as AMT is a controlled substance, while 5-IT is not. The additional compounds studied included controlled and non-controlled substances under Texas law.

To determine if the spectral details were stable and reproducible over time with the goal of capturing the optimal spectrum for library entry, standards for each substance were analyzed via GC-IRD twice daily for five days. Visual as well as library match analysis of each standard's chromatography and vapor phase IR spectra was conducted. Spectra were examined for their reproducibility over time, as well as any visually distinguishing features between closely related isomer sets.

A significant difference was noted between 5-IT and AMT vapor phase IR spectra and chromatography. IR spectra for both standards were found to be highly reproducible over the course of this study. Differences observed in the IR spectra were the sharpness and general peak shape primarily within the fingerprint region. AMT reproducibly suffered poor chromatography whereas 5-IT chromatography was consistently ideal.

The four cathinone controls, 2,3-DMMC, 3,4-DMEC, 3-MMC, and 2-MMC constituted in methanol, initially presented issues with chromatography. Therefore, a basic (0.45 N sodium hydroxide)/hexane extraction was performed and resulted in improved chromatography. It was noted that two of the four cathinone controls (2,3-DMMC and 2-MMC) began to degrade at a faster rate when compared to others during the validation process, resulting in low reproducibility for their IR spectra and lower likelihood of identification via library search. Frequent manipulation of averaged peak areas and background reference areas was required to compensate for decomposition products. Degradation of the injected samples could possibly be due to the instability of the compound itself, method parameters, or interaction of the sample with the reflective coating of the light pipe. Method optimization was attempted by changing a variety of parameters such as split ratios, flow rates, oven programming, and inlet temperatures. Overall, differentiation of these compounds was successful using obtained IR spectra.

Following this study, the analysis of forensic casework containing these substances resulted in unambiguous identification, allowing the laboratory to confirm which isomer was present in a given sample. These cases, along with other factors relating to positive identification via GC-IRD, will be discussed.

Drug Analysis, Regioisomers, GC-IRD

B129 Capillary Electrophoresis/Mass Spectrometry (CE/MS) as an Effective Tool for Identification of Illicit Drugs and Their Optical Isomers

Mehdi Moini, PhD, George Washington University, Dept of Forensic Sciences, 2100 Foxhall Road, NW, Washington, DC 20007; Christopher M. Rollman, BS, George Washington University, 2100 Foxhall Road, NW, Somers Hall, L14, Washington, DC 20007; Mike Hitchcock, MS, U.S. Postal Inspection Service, Forensic Laboratory Services, 22433 Randolph Drive, Dulles, VA 20104-1000; and Ioan Marginean, PhD, George Washington University, 2100 Foxhall Road, NW, Somers Hall L14C, Washington, DC 20007*

After attending this presentation, attendees will better understand the application of CE/MS for the separation of chiral compounds of forensic importance.

This presentation will impact the forensic science community by suggesting a rapid and highly sensitive method to separate and identify drugs and their optical isomers.

Many pharmaceutical and illicit drugs have structural and optical isomers. For some illicit drugs, identification of these is essential since scheduling and sentencing could vary based on which isomer of a compound is present in a sample. For example, amphetamine and Lyric® (S-pregabalin) are drugs which may be legally available as a single optical isomer. Also, information about the route of synthesis and country of production can be gained from isomer analysis. Amphetamines and cathinones can be synthesized through several routes which may result in different isomer quantities in the final drug. While Gas Chromatography/Mass Spectrometry (GC/MS), High-Performance Liquid Chromatography (HPLC), and Ultra High-Performance Liquid Chromatography/Mass Spectrometry (UHPLC/MS) are capable of separating some structural isomers, they require chiral derivatization or chiral columns for separation of optical isomers; however, these procedures are time-consuming and/or expensive. Capillary Electrophoresis/Ultraviolet (CE/UV) and High-Performance Liquid Chromatography/Ultraviolet (HPLC/UV) are also used for structural and optical isomer identification, but they lack confirmatory compound identification capability. Therefore, the forensic community will benefit from a confirmatory technique that can provide structural and optical isomer identification with ease. This presentation introduces a simple CE/MS technique for identification of structural and optical isomers of illicit drugs using (+)-(18-crown-6)-2,3,11,12-tetracarboxylic acid (18-C-6-TCA) and Cyclodextrin (CD) derivatives as an effective background electrolyte that can provide optimum separation and high sensitivity detection of chiral compounds.

Analyses were performed using narrow (<20µm inner diameter), underivatized fused silica capillaries utilizing a porous tip for CE/MS interface. Various chiral selectors such as 18-C-6-TCA and CD derivatives were used as background electrolytes for CE/MS analyses. Samples were injected hydrodynamically and separations occurred at 25kV.

The separation of R- and S-pregabalin was achieved using only 18-C-6-TCA in approximately ten minutes. Quantitative studies showed a linear trend across three orders of magnitude between 1µg/mL and 1,000µg/mL. Furthermore, analysis of a Lyrica® tablet resulted in only one electrophoretic peak confirming the compound optical purity. In addition to pregabalin, the optical isomers of cathinone and nor-mephedrone (metabolite of mephedrone) formed complexes with 18-C-6-TCA, which allowed for their separation. The optical isomers of amphetamine and methamphetamine were separated using highly sulfated γ-CD. Future work includes analyzing more drugs whose chirality is important either due to scheduling or for intelligence purposes.

Using a background electrolyte containing 18-C-6-TCA or CD, CE/MS allows for the separation and high sensitivity detection of isomers.

Illicit Drugs, Optical Isomers, CE/MS

B130 Characterization of Synthetic Phenethylamines Using High Resolution Mass Spectrometry (HRMS)

Alexandria Anstett, BS, 2900 Northwind Drive, Apt 726, East Lansing, MI 48192; Fanny Chu, BS, 35-11 Linden Place, Apt 3F, Flushing, NY 11354; and Ruth Waddell Smith, PhD, Michigan State University, School of Criminal Justice, 560 Baker Hall, East Lansing, MI 48824*

After attending this presentation, attendees will understand the advantages of HRMS for the analysis of synthetic designer drugs, specifically synthetic phenethylamines. Attendees will learn how the mass defect obtained via HRMS can be used to characterize these compounds according to structural class.

This presentation will impact the forensic science community by providing a method to characterize unknown synthetic designer drugs according to structural class. This method is especially useful in the characterization of novel designer drug analogs for which no reference standard is yet available.

A number of different classes of synthetic designer drugs are known, including synthetic cannabinoids, phenethylamines, and cathinones. Compounds within each class often share a core structure and differ only in the position or identity of substituents. When a compound is regulated, a new analog often appears on the market. This analog exhibits similar psychoactive effects but because the structure is slightly different, the analog may not regulated under current legislation.

Samples submitted to the laboratory that may or may not contain controlled substances are analyzed by Gas Chromatography/Mass Spectrometry (GC/MS). This technique satisfies the Scientific Working Group for the Analysis of Seized Drugs recommendations, allowing definitive identification of controlled substances through a comparison of the mass spectrum obtained for the submitted sample to that of a reference standard. The GC/MS instruments used are typically configured with Electron Ionization (EI) and a single quadrupole mass analyzer (qMS). Electron ionization results in substantial fragmentation and the fragment ions observed can be used toward structural elucidation to identify the compound. The single qMS gives unit resolution, resulting in nominal mass data which is sufficient for identification of most controlled substances; however, synthetic designer drugs pose challenges that make definitive identification using GC/qMS difficult. First, isomers have the same nominal mass, making distinction by GC/qMS alone problematic. Second, because novel designer drug analogs appear on the market frequently, reference standards are often not immediately available, making identification challenging.

The objective in this research was to address the above issues by investigating the applicability of HRMS as a tool to aid in the identification and characterization of synthetic phenethylamines. Using HRMS, the accurate mass of each fragment ion is measured, providing additional understanding about the fragmentation pathway of the compound. This knowledge of the fragmentation behavior can be used to determine the compound structure with a high degree of certainty and therefore distinguish isomers. Further, accurate mass data is used to determine the mass defect of a compound, defined as the difference between the accurate and nominal mass. Compounds with similar core structure have similar mass defects. Thus, the mass defect can be used to determine the structural class of a new analog, which is useful in cases where no reference standard exists.

In this research, a set of synthetic phenethylamines from different subclasses (e.g., 2C and NBOMe) was investigated. Reference standards were prepared in methanol (1mg/mL) and analyzed in replicate by GC/qMS and by GC/Time-of-Flight (TOF) MS. Both instruments use EI; however, the TOF is a high-resolution mass analyzer, affording accurate mass data. For each standard, GC/qMS and GC/TOF/MS data were compared and showed similar fragmentation patterns. For example, characteristic fragment ions for 2C-E were observed at m/z 209Da, 180Da, and 165Da via GC/qMS and at m/z 209.1457Da, 180.1185Da, and 165.0947Da via GC/TOF/MS. The accurate mass data were used to confirm fragmentation pathways of the phenethylamines from which distinction of isomers such as 2C-E and 2C-G was possible.

For each standard within a subclass, the mass defects of the molecular ion and characteristic fragment ions were determined. From this, a range of mass defects representative of the core structure was calculated. For example, a mass defect range for the 2C subclass of 133.88±26.02mDa was determined based on the molecular ion for all 2C phenethylamines in the data set. An additional set of phenethylamine standards was used to evaluate the efficacy of the mass defect range for characterization. Successful classification was achieved despite the presence of some false positives and false negatives.

This presentation demonstrates the utility of HRMS in the identification and characterization of synthetic phenethylamines, focusing on the potential of mass defect as a characterization tool.

Synthetic Designer Drugs, Mass Spectrometry, Mass Defect

B131 Differentiation of Cathinone Isomers Using High Resolution Collision-Induced Dissociation Mass Spectrometry (CID/MS)

Cynthia Kaeser, MS, 162 Martin Avenue, Livermore, CA 94551; A. Daniel Jones, PhD, 219 Biochemistry, East Lansing, MI 48824; and Ruth Waddell Smith, PhD, Michigan State University, School of Criminal Justice, 560 Baker Hall, East Lansing, MI 48824*

After attending this presentation, attendees will understand how CID/MS fragmentation of cathinones can be used to differentiate isomers and how the underlying fragmentation mechanisms lead to the observed differences.

This presentation will impact the forensic science community by demonstrating the differentiating power of CID/MS for isomer identification. This presentation will provide better understanding of fragmentation mechanisms that can also be applied to analogs when no standard is available for comparison.

With the increased availability and subsequent regulation of synthetic designer drugs such as cathinones, clandestine chemists continue to produce new unregulated analogs of these compounds. These analogs keep many of the same structural features that yield the desired biological response but contain slight structural differences to avoid regulation. Isomers are especially difficult to distinguish because these analogs have the same chemical formula but with different structural arrangements. Typical analysis of a suspected cathinone by a forensic laboratory uses Gas Chromatography/Mass Spectrometry (GC/MS) with the Electron Ionization (EI) MS spectra compared to reference standards.

However, positive identification of new analogs by GC/MS is complicated by the lack of molecular ion and available reference standards. In these cases, several analytical techniques are necessary for identification, a difficult requirement to meet given the high caseloads and lack of advanced instrumentation available in many laboratories. As an alternative to using multiple instruments, CID/MS can be performed with high-mass resolution while using multiple collision energies for fragmentation. The main advantages of this technique over EI/MS are twofold. First, varying the collision energy used produces both the intact ion and a series of increasingly smaller fragments as the energy is increased. This reveals more details about the structural arrangement of an isomer than using a single collision energy. Second, high-mass resolution improves confidence in molecular formula assignment for positive identification.

While part of a larger study of cathinone fragmentation, three cathinone isomers were selected for this presentation: butylone, ethylone, and the 2,3-ethylone isomer. Butylone and ethylone are in Schedule I of the Controlled Substances Act while the 2,3-ethylone isomer is currently unregulated. Butylone and ethylone differ in the length of hydrocarbon chains at the alpha position and on the amine while the 3,4-methylenedioxy substitution on the aromatic ring is the same for both. The 2,3-ethylone isomer has the same hydrocarbon arrangement as ethylone, but the methylenedioxy group is at the 2,3-position.

Each standard was prepared at a concentration of 5ug/mL in methanol and directly injected into a quadrupole time-of-flight mass analyzer with Electrospray Ionization (ESI) and a leucine-enkephalin reference compound to improve mass accuracy. Fragmentation of each isomer was observed using collision energies of 10eV, 20eV, and 40eV. Resulting mass spectra were interrogated and the molecular formulas of major fragments were determined using their exact masses (four decimal places, <20ppm mass error). The molecular formulas and the voltage of appearance for each isomer's fragments were used to generate flowcharts for identification of common fragmentation pathways. These pathways provide insight into the positions of functional groups on the molecule allowing isomers to be distinguished.

While some differences in fragmentation were observed at the lowest collision energy, more discriminating features were observed at the higher energies. For example, at 10eV the loss of the amine group from the intact molecule distinguished butylone from the ethylone isomers. The fragment masses alone could not distinguish between the two ethylone isomers, although some differences in the relative abundances of each fragment were present. At higher voltages, additional fragments were identified by their exact masses to include losses of both odd and even electron species. While radical (odd electron) losses are less common for ESI than for EI, such species are resonantly stabilized by the aromatic ring. Radical fragments, including losses of radical methyl and ethyl groups, were the most differentiating between the two ethylone isomers.

This presentation will demonstrate the use of CID/MS as a single technique for successful isomer differentiation of cathinones. While this presentation focuses on a limited subset of cathinones, the process for using the observed fragmentation mechanisms for the identification of new cathinone analogs will also be discussed.

Cathinones, Mass Spectrometry, Designer Drugs

B132 The Effects of Water Immersion on the Recovery of DNA From Human Remains

Ema H. Graham, University of New Haven, 300 Boston Post Road, West Haven, CT 06516; Shanae J. Armstrong, MS, 2432 Oceancrest Boulevard, Far Rockaway, NY 11691-1929; and Michael S. Adamowicz, PhD, University of New Haven, Dept of Forensic Science, 300 Boston Post Road, West Haven, CT 06516*

After attending this presentation, attendees will better understand the effects of short duration (≤1 month) immersion in different types of water on human remains. This study presents data regarding the quantity and quality of DNA recovered from human soft tissue and bone after immersion in fresh, brackish, and salt waters. Data is shown for immersion periods ranging from 24 hours to 1 month in each type of water.

This presentation will impact the forensic science community by demonstrating that the quantity and quality of DNA recovered from different tissues is affected by both the duration of immersion and by the type of water in which the remains are immersed. This data will allow forensic scientists to better predict the success of DNA typing from human remains based on estimated time of immersion and water type, thus assisting in producing the most complete Short Tandem Repeat (STR) profiles possible.

There are numerous incidents that involve human remains in water and, as a result, identification of the individuals from these remains is of great importance. The purpose of this study was to determine if a DNA profile could be retrieved from human bone and soft tissue immersed for varying periods of time. It also assessed the effects of different water types on recovering usable DNA from the tissue samples. Human rib and associated muscle/connective tissue samples were collected from multiple individuals during autopsy. The soft tissue was separated from the bones, which were then equally sectioned, and both were immersed in salt water (~35ppt), brackish water (~10ppt), or fresh water (~0ppt) for intervals of 24 hours, 48 hours, 72 hours, 96 hours, 1 week, and 1 month (31 days). Time-control samples were also used for each of the different intervals, with no immersion in water. A time zero sample for each tissue type was run for each experiment to ascertain the approximate starting quantity and quality of the DNA.

DNA from the bone and soft tissue samples was extracted using QIAamp®, quantified with Quantifiler®, amplified via PowerPlex® 16 HS, and analyzed using standard methods of STR analysis employed in forensic laboratories. The DNA profiles generated were compared to the reference samples to determine how many of the alleles present were concordant with the references. DNA quality in each sample was assessed by averaging the number of heterozygous loci with peak height balances that were ≥70% and by comparing the average peak heights at loci D3S1358 and FGA for each immersion time interval.

Resulting data established that DNA degradation increased as time increased. All samples yielded full STR profiles after 24 hours of immersion with no significant DNA degradation present. After 48 hours of immersion, some samples, particularly bone in salt and brackish water, began to show allele and/or locus drop-out and heterozygous peak height imbalance indicating DNA degradation; however, full profiles were not uncommon at 48 hours. There was a significant reduction in the DNA quantity and quality in all sample types between the 48-hour and 72-hour immersion times. After 72 or more hours of immersion, some samples yielded full profiles, but locus drop-out and heterozygous peak height imbalance were common. While DNA degradation was severe after one month of immersion, typable STR results could still be produced in some samples. The results for soft tissue samples showed that after one month of immersion, samples in salt water had the highest DNA loss but produced the best quality DNA as measured by heterozygous peak height balance as compared to the same immersion time in fresh or brackish waters. After one month of immersion, bone samples in fresh water had the lowest DNA loss and produced the best quality DNA as compared to the same immersion time in salt or brackish waters.

DNA, Human Remains, Water Immersion

B133 Comparison of Three Filtration Devices for Recovery of Low Level and Degraded DNA

Nichole M. Tuscher, MFS, Contra Costa County Criminalistics Laboratory, 2530 Arnold Drive, Martinez, CA 94553; Ismail M. Sebetan, MD, PhD*, National University, Forensic Sciences Program, 11255 N Torrey Pines Road, La Jolla, CA 92037-1011; and Paul Stein, PhD*, National University, Forensic Science Program, 11255 N Torrey Pines Road, La Jolla, CA 92037*

After attending this presentation, attendees will understand the use of filter devices available for DNA recovery and which device may produce a better DNA yield for low level and compromised samples and will assist the DNA analyst in making decisions with respect to delicate forensic evidence. This presentation is based on an in-house comparison of the Microcon® 30 MW, Vivacon® 30 MW, and the NucleoSpin® devices for DNA capture using a phenol-chloroform extraction method.

This presentation will impact the forensic science community by demonstrating that an appropriate filter device can impact the outcome of DNA recovered for low level and compromised samples.

There is a strong demand in forensic DNA to analyze smaller and smaller amounts of DNA in casework. Many of these cases may involve "touch" DNA that may have inhibitors present. While phenol extraction is more labor intensive than robotic extraction methods, it permits the analyst to use a filter device to reduce the volume of the DNA extract into the small amplification volume required and increase the chances of template DNA recovery.

The Microcon®, Vivacon®, and NucleoSpin ® products all use a membrane-based filtration device for DNA capture. The Microcon® device can hold up to 500µl of volume at a time, the NucleoSpin® can accommodate up to 400µL of volume, and the Vivacon® can hold up to 2mL. All three devices use centrifugal force to filter the volume of the extract and washing buffer through the membrane. The Microcon® and Vivacon® require inversion of the membrane and centrifugal force to release the DNA in the elution buffer. The NucleoSpin® uses a binding buffer which permits washing of the membrane to remove inhibitors and then an elution buffer to release the DNA. The centrifugal time required to spin the buffers and wash is significantly shorter than the Microcon® or Vivacon®.

A series of experiments was set up in a side-by-side comparison of all three devices. An Applied Biosystems® 7500 Real-Time Polymerase Chain Reaction (RT-PCR) instrument with the Applied Biosystems® Quantifiler® Duo Kit was used to estimate the amount of DNA recovered. Only the inhibited and degraded samples were amplified with the Applied Biosystems® Identifiler® Kit and analyzed with an Applied Biosystems® 310 Genetic Analyzer. When comparing known amounts of low level DNA, the Nucleospin® had nearly twice the DNA recovery (91.5pg) compared to the Microcon® (48.6pg), and Vivacon® (50.8pg) at the lowest known concentration of DNA (111.2pg). As the concentrations increased, the Microcon® was comparable and then exceeded the NucleoSpin® at the lowest concentration 111.2pg of known DNA.

Inhibition was studied using different concentrations of soil and denim dye solutions added to the samples after digestion and before extraction since these are commonly encountered inhibitors. The Microcon® and Vivacon® were not able to produce any allele calls whereas the NucleoSpin® produced full profiles at all concentration levels. A degraded blood stain was diluted to create known low level samples to test the recovery ability of the Nucleospin® and Microcon®. The NucleoSpin® generated partial profiles with three different dilutions and the Microcon® produced one partial profile for one dilution and a few allele calls with the remaining dilutions.

In conclusion, the NucleoSpin® was not only more effective at removing inhibitors as anticipated by the literature but was also better at recovering degraded DNA than the Microcon®. The added benefit of the reduced amount of sample handling and shorter centrifuge time makes the NucleoSpin® product a better concentration device for low level and compromised DNA samples.

Low Level DNA, PCR Inhibitors, DNA Filtration Device

B134 Selective Degradation Using the Erase™ Sperm Isolation Kit and PrepFiler® Purification

Melissa D. Moore, BS, Orange County Crime Lab, 320 N Flower Street, Santa Ana, CA 92703; Richard A. Gustilo, Orange County Crime Laboratory, 320 N Flower Street, Santa Ana, CA, CA 92703; Mary M. Hong, BS, Orange County Sheriff-Coroner, 320 N Flower Street, Santa Ana, CA 92703; Ruth H. Ikeda, PhD, Orange County Sheriff-Coroner, 320 N Flower Street, Santa Ana, CA 92703; Stacy Vallercamp, 300 N Flower Street, Santa Ana, CA 92703; Ismail M. Sebetan, MD, PhD*, National University, Forensic Sciences Program, 11255 N Torrey Pines Road, La Jolla, CA 92037-1011; and Paul Stein, PhD*, National University, Forensic Science Program, 11255 N Torrey Pines Road, La Jolla, CA 92037*

After attending this presentation, attendees will understand the benefits of using selective degradation in place of the standard differential extraction method when processing sexual assault evidence. Attendees will learn how selective degradation can be used to replace the standard differential extraction method to obtain a single-source male DNA profile and how the process can be partially automated by integrating the Erase™ Sperm Isolation Kit with the PrepFiler® DNA Extraction Kit.

This presentation will impact the forensic science community by introducing a reliable procedure that can be successfully used for differential extraction of DNA from very challenging forensic samples in a shorter time and with less intensive labor.

This presentation discusses how selective degradation can be used to replace the standard differential extraction method to obtain a single-source male DNA profile from post-coital vaginal swabs containing sperm. Differential extraction is traditionally used to separate and purify the sperm cell DNA from the epithelial cell DNA. Differential extraction is time consuming and requires intensive work by the analyst. With the high number of sexual assault cases and increasing backlog of sexual assault kits, it is necessary to implement a simpler method to separate sperm cell DNA from epithelial cell DNA.

Selective degradation is accomplished by selectively destroying epithelial DNA using a nuclease, while sperm DNA remains intact inside the sperm cell. The Erase™ Sperm Isolation kit provides crime laboratories with the components necessary to perform selective degradation on sexual assault evidence.

Once the epithelial cell DNA and sperm cell DNA are separated using selective degradation, the DNA sample must be purified. The Erase™ protocol states that the DNA sample can be purified using ethanol precipitation, size filtration, or QIAGEN® EZ1 DNA purification. This study determined that the PrepFiler® DNA Extraction kit can also be used to purify DNA samples previously digested with the Erase™ Sperm Isolation kit. Although the selective degradation portion of this method is performed manually, the DNA purification portion of this method can be performed automatically using the Tecan Freedom EVO® 150, which is a robotic liquid handler. The usage of a robotic liquid handler greatly reduces the amount of analyst hands-on time, variability, and exposure to harmful chemicals, such as phenol-chloroform. Once purified, the DNA sample can be used in further downstream applications.

Vaginal swabs were first collected zero to one hour after intercourse and for the purpose of this study are considered high-sperm samples. Vaginal swabs were collected again between 21 and 25 hours after intercourse and considered low-sperm samples. Stained microscope slides were prepared to identify the presence of spermatozoa. Microscopic identification of spermatozoa confirmed that each of the four samples tested contained a low amount of sperm.

The low-sperm post-coital swabs collected at 21 to 25 hours were digested using the Erase™ Sperm Isolation kit protocol and purified using the automated PrepFiler® DNA Extraction kit. After purification, the sperm and non-sperm fractions of the DNA sample were quantitated, amplified, and typed using Identifiler Plus®. The sperm fraction DNA profiles resulted in single-source male DNA profiles 87.5% of the time. For the purposes of this study, a DNA profile was considered single-source when all loci were identified as originating from one individual and where the minor peak represented was less than 20% at each locus. If the sperm fraction DNA profile had female signals between 20% and 80% of the total signal at a locus, it was considered a mixed profile.

Experimental findings show that the Erase™ Sperm Isolation kit can successfully separate epithelial cell DNA from sperm cell DNA located on post-coital vaginal swabs containing a low amount of sperm. Results indicate that the Erase™ Sperm Isolation kit can be integrated with the PrepFiler® DNA Extraction kit to separate and purify epithelial cell DNA from sperm cell DNA.

This study shows that selective degradation combined with automated DNA purification can be used in place of the standard differential extraction method on sexual assault evidence containing a mixture of DNA from the victim, in the form of epithelial cells, and from the perpetrator, in the form of spermatozoa. Using selective degradation as opposed to the standard differential extraction method when processing sexual assault evidence can conserve time and effort and result in better sperm fraction DNA profiles.

Differential Extraction, Selective Degradation, Sexual Assault Evidence

B135 Evaluation of the QIAGEN® Investigator 24Plex Polymerase Chain Reaction (PCR) Kit for Amplification of Forensic Samples

Clinton D. Buchanan, PhD, 4930 N 31st Street, Forest Park, GA 30297; and Joel D. Sutton, MSFS, 4930 N 31st Street, Forest Park, GA 30297-5205*

The goal of this presentation is to provide attendees with information regarding performance of the QIAGEN® Investigator 24plex PCR kit during assessment studies addressing sensitivity, reproducibility, precision, mixtures, contamination, concordance, and non-probative case-type samples.

This presentation will impact the forensic science community by providing insight to laboratories considering implementation of expanded core loci PCR kits for forensic casework applications.

The QIAGEN® Investigator 24plex QS kit is a recently National DNA Index System (NDIS) -approved Short Tandem Repeat (STR) amplification kit used for human identification applications. The kit allows for multiplex amplification of the Combined DNA Index System (CODIS) core loci, the European Standard Set (ESS) markers, SE33, DYS391, D2S1338, D19S433 and Amelogenin. Laboratory studies of the QIAGEN® Investigator 24plex QS were performed to determine the efficacy of the kit for amplification of forensic samples. DNA samples were amplified using the standard cycling protocol, and sample amplicons were processed on the Applied Biosystems® 3500xl genetic analyzer following steps outlined in the Investigator 24plex QS handbook (rev. 08/2014). GeneMapper ID-X_v1.2 panels, bins, and stutter files for the Investigator 24plex QS kit were provided by QIAGEN® (Investigator_TemplateFiles_GeneMapper_ID-X_v7). These default files were used for data analysis; however, default stutter ratios for some loci (provided in the Investigator Template GeneMapper ID-X _v7 files) were modified based on maximum stutter findings observed.

The experiments focused on sensitivity and mixtures prepared from DNA sourced commercially and via in-house extraction methods. Comprehensive mixture studies were conducted. Additional work included reproducibility, concordance, contamination assessment, non-probative case-type samples, precision, and qualifying samples (National Institute of Standards and Technology (NIST) standard reference material) studies. Artifacts observed throughout the course of testing included elevated baseline, spectral pull-up, elevated stutter, and occasional spikes. DNA template amounts ranging from 0.008ng to 1.25ng from multiple sources were included in sensitivity studies. Admittedly, elevated stutter is not unexpected in lower-level DNA samples; however, stutter values exceeding filter values provided in the Investigator Template GeneMapper ID-X _v7 files were observed in samples associated with DNA template amounts ≥0.125ng. In addition, allelic drop-in of a 14 allele at locus D8S1179 was observed in one 9948 sensitivity sample at 0.016ng; however, this is not unexpected when working with lower-level DNA samples. Heterozygous peak height ratios were generally ≥50% in sensitivity samples targeting ≥0.125ng of DNA, and complete profiles were generally observed in samples targeting ≥0.063ng of DNA. The data gathered and analyzed from the laboratory studies of the QIAGEN® Investigator 24plex QS kit supports the PCR kit as being a robust and reliable tool for obtaining STR results for the expanded CODIS core loci set.

QIAGEN® Investigator 24-Plex, PCR Kit, Forensic Samples

B136 Working With Challenging Samples: An Independent Assessment of the Relative Performance of the Promega® Fusion™ and InnoGenomics® InnoTyper™ Kit With Probative Samples

James Anstead, PhD, 840 Research Parkway, Ste 551, Oklahoma City, OK 73104; Erica Reynaga, MS, DNASolutions, 840 Research Parkway, Ste 551, Oklahoma City, OK 73104; Kelsy Lowther, MS, DNASolutions, 840 Research Parkway, Ste 551, Oklahoma City, OK 73104; and Brandt G. Cassidy, PhD, 840 Research Parkway, Ste 551, Oklahoma City, OK 73104*

After attending this presentation, attendees will better understand the relative merits of the InnoGenomics® InnoTyper™ and Promega® Fusion™ kits for the analysis of challenging forensic samples.

This presentation will impact the forensic science community by providing information on gaining the most information from challenging forensic samples.

Traditional analysis of challenging forensic samples often relies on mitochondrial markers, due to their relative stability and high copy number; however, there are considerable drawbacks to this approach including the lack or recombination and the absence of paternal contribution. Therefore, the generation of reliable nuclear profiles from degraded samples continues to be increasingly important for forensic testing.

Recently, based in part on the recommendations from the Federal Bureau of Investigation (FBI), kit manufacturers have released multiplexes with heightened sensitivity and robustness when compared to standard genomic marker systems. These systems have been optimized for improved performance with challenging samples. The Promega® Fusion™ system interrogates 22 autosomal Short Tandem Repeats (STR), the amelogenin locus for gender identification, and a gender confirmatory marker on the Y chromosome. Eight of the STR markers produce alleles less than 200 base pairs in length, increasing the likelihood of producing results from compromised forensic samples and the chance of obtaining probative data from forensic evidence. The development of markers based on Retrotransposable Insertion Polymorphisms (RIPs) enables additional information to be retrieved from the most highly degraded and inhibited samples, including bone and hair shafts. Innogenomics® InnoTyper™ 21 system utilizes small amplicon DNA typing of repetitive Alu sequences from 20 loci and amelogenin in which each locus is scored for the presence of a stable heritable insertion. This biallelic system has been reported to produce interpretable genetic profiles with as little as 60 picograms of input DNA from compromised and challenging samples. This study assesses the sensitivity and amount of probative data obtained using the Promega® Fusion™ kit and the Innogenomics® InnoTyper™ 21 kit on low-yielding, highly degraded, and challenging forensic samples, including bone of varying age and condition, hair shafts, and touch samples.

InnoTyper™, Fusion™, STR

B137 Faux-Dis: An Online, Searchable DNA Database Available for Educational Purposes

Ashley Hall, PhD, University of Nebraska - Lincoln, 103 Entomology Hall, Lincoln, NE 68583*

After attending this presentation, attendees will better understand a novel, publicly available educational tool.

This presentation will impact the forensic science community by introducing a powerful research and teaching tool.

The United States national DNA database, Combined DNA Index System (CODIS), contains more than ten million genetic profiles originating from convicted offenders, missing persons, and crime scene evidence and is searchable only by authorized governmental agencies. Due to the private nature of the data it contains, educators do not have access to this powerful database for teaching purposes. Therefore, there is currently a lack of a searchable human DNA profile databases available for use in the research laboratory or in the classroom. If it were available, such a database could be a valuable tool in the analysis of large data sets, for use in forensic laboratory exercises, and in answering questions about population genetics. Therefore, the development of a searchable DNA database modeled after CODIS that can be used by educators nationwide was initiated. Called Faux-Dis, it will allow students to gain hands-on experience and knowledge in the manipulation of large data sets, and it would support calculations in population genetics problems. The development of this database is a beneficial contribution to the field of forensic science because it has the potential to foster a nationwide collaboration and can be used for graduate and undergraduate education and training.

To initiate this project, human biological DNA samples containing buccal epithelial cells were collected from donors using a sterile cotton swab. DNA was isolated and purified using an organic extraction. Each sample was then quantified using the Qubit® fluorometer. The multiplex Polymerase Chain Reaction (PCR) PowerPlex® 16 was used to amplify the DNA at 16 loci, which were targeted by specific, fluorescently labeled primers. The PCR products were run through capillary electrophoresis on the 3130 Genetic Analyzer to generate a DNA profile. This profile was visualized as a plot of Relative Fluorescent Units (RFU) against size in base pairs (bp) for each of the 16 regions (loci) amplified by PCR. Each locus has two alleles, giving either one or two peaks. The size in bp determines which alleles are present. Each allele can be determined by comparing to an allelic ladder, thus allowing the profile to be genotyped. The generated profiles were entered into the database.

To date, a standard workflow for processing samples has been established and 100 profiles have been added to the database. In the future, the database will be transferred to an online searchable format, and collaborators from other universities and colleges will be invited to submit samples for analysis to form a large consortium of participants.

CODIS, Database, Education

B138 Human Short Tandem Repeat (STR) Profiles From Blood-Fed Mosquitos

Jared Latiolais, MSc, 10430 Furnace Road, Lorton, VA 22079; Dane T. Plaza, BS, 10430 Furnace Road, Ste 107, Lorton, VA 22079; Andrew B. Feldman, PhD, 11100 Johns Hopkins Road, Laurel, MD 20723-6099; Mobolaje Okulate, PhD, University of Maryland Eastern Shore, 30665 Student Services Center Lane, Princess Anne, MD 21853; Nirbhay Kumar, Louisiana State University, Baton Rouge, LA 70803; and Robert A. B139 Examining the Contribution of Sampling to Peak Height Imbalance in Low Template DNA Samples Using a Single-Tube Extraction Protocol

Thutrang Nguyen, BA, 221 Massachusetts, #708, Boston, MA 02115; and Robin W. Cotton, PhD, Boston University School of Medicine, Biomedical Forensic Sciences, 72 E Concord Street, R 806, Boston, MA 02118*

After attending this presentation, attendees will understand that both pre-Polymerase Chain Reaction (PCR) sampling and PCR chemistry contribute to peak height imbalance as shown experimentally using a single-tube extraction and direct amplification protocol.

This presentation will impact the forensic science community by experimentally showing the contribution of pre-PCR sampling to peak height imbalance.

The developments of the PCR and the Short Tandem Repeat (STR) multiplex kits increased the ease and lowered the time and sample quantity required for Deoxyribonucleic Acid (DNA) typing compared to previous methods; however, the amplification of such a low mass of DNA can lead to increased stochastic effects, such as Allele Drop-Out (ADO) and heterozygous Peak Height (PH) imbalance, which make it difficult to determine the true donor profile. These stochastic effects are believed to be due to: (1) pre-PCR sampling from pipetting and sample transferal of dilute samples prior to amplification resulting in imbalanced heterozygous allele templates in the amplification reaction; and, (2) the kinetics of the PCR process in which there may be uneven amplification of heterozygous alleles during early PCR cycles when few target templates are initially available.

This study examines the contribution of PCR chemistry and pre-PCR sampling errors on stochastic effects by utilizing a single-tube DNA extraction and direct amplification method. Cells were collected into tubes using the McCrone Associates, Inc. cell transfer method, which allowed for approximation of DNA mass without quantification. The forensicGEM® saliva kit was used to lyse the cells and inactivate nucleases without inhibiting downstream amplification. The samples were then directly amplified with the AmpFℓSTR® Identifiler® Plus PCR Amplification kit. These samples should only show the effects of PCR chemistry since pipetting and tube transferal steps prior to amplification were removed with the expectation that equal numbers of heterozygous alleles are present in the sample pre-amplification. Comparisons of PH imbalance were made to samples extracted with forensicGEM® but had one or more pipetting and tube transferal steps prior to amplification; thus, these samples would exhibit the effects of both pre-PCR sampling and PCR chemistry errors and inefficiencies. Results indicate the imperfections observed in PH ratios are a combination of sampling and PCR-generated stochastic effects.

Peak Height Ratio, Low Template DNA, Single-Tube Extraction

B140 Working to Solve Compatibility Issues Between Impression Enhancement and DNA Analysis

Jessica Zarate, MS, 36600 Schoolcraft Road, Livonia, MI 48150; and Jodi Lynn Barta, PhD, Madonna University, 36600 Schoolcraft Road, Livonia, MI 48150*

After attending this presentation, attendees will be provided with research that explores the need for collaborative efforts to maximize evidence potential in order to provide both impression details and DNA profiles for evidence samples deposited in biological fluids. Highlighted in this presentation are the data generated during National Institute of Justice (NIJ) -funded research that uses Zar-Pro™ fluorescent blood lifting strips for enhancement and preservation along with common DNA extraction techniques to generate DNA profiles from impression evidence that has been lifted.

This presentation will impact the forensic science community by showing how DNA is preserved and can be retrieved from impression evidence lifted and enhanced using Zar-Pro™ fluorescent blood lifting strips, thus simplifying collection and preservation while expanding the utility of impression enhancement methods including DNA analysis, which could have the potential to change the way technicians approach crime scene evidence.

Impression evidence, deposited in both blood and non-blood biological fluids, is a common component at many crime scenes. Current fluorogenic enhancement methods for impression evidence can be problematic for DNA preservation and are often impractical for crime scene use due to their toxicity. This may result in a situation in which a crime scene technician must make a decision during evidence collection either to enhance the impression (potentially damaging the DNA evidence) or to gather the DNA evidence (possibly destroying the impression evidence). Zar-Pro™ fluorescent blood lifting strips have been successful in lifting, enhancing, and preserving bloody impression evidence. They provide a highly sensitive method for processing and fluorogenically enhancing bloody impression evidence that can be preserved and utilized over long time intervals; however, the viability of subsequent DNA analyses has not been established.

This research explores the need for collaborative efforts to maximize evidence potential in order to provide both impression details and DNA profiles for evidence samples deposited in biological fluids. Highlighted in this presentation are the data generated during NIJ-funded research that uses Zar-Pro™ fluorescent blood lifting strips for enhancement and preservation along with common DNA extraction techniques to generate DNA profiles from impression evidence that has been lifted. During the initial phase of the project, more than 1,200 impressions were made in five biological fluids on a series of seven substrates that range from non-porous to semi-porous to porous. In order to determine the viability of the DNA over time when fixed to the Zar-Pro™ fluorescent blood lifting strips, trials were established to test one-month, three-month, six-month, and twelve-month intervals. The goal of this project was to test the viability of DNA in evidence processed with Zar-Pro™ fluorescent blood lifting strips and to develop and optimize a DNA extraction protocol in an effort to develop a simple, time- and cost-effective, non-toxic method that is safe for use at crime scenes and provides opportunities for subsequent DNA recovery suitable for use in forensic science laboratories. Preliminary results are encouraging and indicate that DNA is sufficiently preserved and can be retrieved from impression evidence lifted and enhanced using Zar-Pro™ fluorescent blood lifting strips. Research is ongoing; however, the data generated suggest that simplifying collection and preservation while expanding the utility of impression enhancement methods to include DNA analysis could change the way technicians approach crime scene evidence.

Impression Enhancement, DNA Preservation, DNA Analysis

B141 Updates to the Forensic Research/Reference on Genetics Knowledge Base (FROG-kb) Database

Kenneth Kidd, PhD, Yale University School of Medicine, Dept of Genetics, 333 Cedar Street, New Haven, CT 06520; Haseena Rajeevan, PhD, Yale University School of Medicine, 333 Cedar Street, New Haven, CT 06520; Katherine N. Moore, MS, RTI International, 3040 E Cornwallis Road, Research Triangle Park, NC 27709; Richard Satcher, MS, RTI International, 3040 E Cornwallis Road, Research Triangle Park, NC 27709; Patricia A. Foley-Melton, PhD, RTI International Center for Forensic Science, 3040 E Cornwallis Road, Bldg 3, Rm 201, Research Triangle Park, NC 27709; and Jeri D. Ropero-Miller, PhD, RTI International, 3040 Cornwallis Road, PO Box 12194, Bldg 7, Rm 211, Research Triangle Park, NC 27709*

After attending this presentation, attendees will have an overview of the capabilities and functionality of the FROG-kb as a resource to make allele frequency data for Single Nucleotide Polymorphisms (SNPs) and other genetic polymorphisms more useful in the forensic field.

This presentation will impact the forensic science community by providing an overview of FROG-kb, recent updates to the database including data and website enhancements, and a visual of how to utilize FROG-kb.

FROG-kb (http://frog.med.yale.edu/FrogKB/) is a database that provides tools through its web interface for comparing user-provided data with underlying allele frequencies in populations and serves as a teaching and research web interface. Current SNP panels on FROG-kb include Individual Identification Single Nucleotide Polymorphisms (IISNPs), Ancestry Inference Single Nucleotide Polymorphisms (AISNPs), and Phenotype Interference Single Nucleotide Polymorphisms (PISNPs). The data used in FROG-kb calculations derive from the Allele Frequency Database (ALFRED) (http://alfred.med.yale.edu), a continually updated database of allele frequency data on SNPs and other genetic polymorphisms. SNPs can be valuable for investigative leads when known profiles using STRs are not available and no hits in databases such as the Combined DNA Index System (CODIS) are identified. These investigative leads provided by SNPs can include ancestry and phenotype inference and individual identification, all of which are provided in the FROG-kb database.

Recent updates to FROG-kb have centered on inputting additional data and website enhancements to provide an organized and easily navigated resource for the forensic community. One of these updates was creating a comprehensive user manual that provides users with step-by-step directions on how to use and search FROG-kb from the different SNP panels available. A short video was created to provide users a visual on navigating and searching FROG-kb along with search examples. This presentation will provide an overview of the new infrastructure to utilize the database for forensic purposes, including a user manual to assist in the process, discussion of the results of searches, and what can be done with the data.

Understanding and utilizing SNPs are important as a new area in the forensic field and FROG-kb serves to provide this to the forensic science community as a user-friendly, free, and web-accessible resource.

Allele Frequency, Database, FROG-kb

B142 Examination of 20 Retrotransposable Polymorphic Insertion/Null (INNUL) Markers for Their Utility in Kinship Testing Using the Commercial Software Program LSAM

AnniLauri Villeme, BS, 311 Eldrid Drive, Silver Spring, MD 20904; Gretchen E. Bartizal, 327 Montpelier Court, Westminster, MD 21157; Becky Hill, MS, 100 Bureau Drive, MS 8311, Gaithersburg, MD 20899; and Michael D. Coble, PhD, 100 Bureau Drive, MS 8312, Gaithersburg, MD 20899-8312*

After attending this presentation, attendees will understand the effectiveness and abilities of using the software program Laboratory Information System Applications (LISA) Statistical Analysis Module (LSAM) to successfully track and manage data and documents, calculate statistics of paternity/kinship analysis, and support direct match comparisons of profiles for the INNUL markers compared to hand-calculated statistics for paternity/kinship analysis in complete and degraded sample profiles.

This presentation will impact the forensic science community by illustrating the benefits and potential of using the LSAM software for the analysis of INNUL markers in kinship and paternity testing. Also, this study examines the impact that INNUL markers have compared to other types of markers such as mitochondrial DNA (mtDNA) or Single Nucleotide Polymorphism (SNP) when testing samples with degraded DNA.

Forensic DNA testing has proven to be a powerful tool for criminal investigations and for identifying human remains via kinship analysis for cases involving mass disasters or missing persons. Short Tandem Repeat (STR) markers most often offer the highest degree of discrimination and speed of analysis by using the Polymerase Chain Reaction (PCR) and capillary electrophoresis to generate DNA profiles. DNA testing for human remains identification is often challenging due to the presence of degraded DNA or inhibitors that affect the PCR reaction. Mini Short Tandem Repeats (miniSTRs) have been engineered to decrease the size of PCR amplicons to improve recovery of DNA fragments in the high molecular weight range of standard STR kits.[1] Additional marker systems such as SNPs, Insertion/Deletion markers (InDels), and mitochondrial DNA (mtDNA) have been successfully used for highly degraded samples.

Retrotransposable Polymorphisms (RP) are found in the human genome as RNA elements that have been reverse transcribed into specific loci as complementary DNA (cDNA) by use of retroposition.[2] RP include the Alu elements Short Interspersed Nuclear Elements (SINEs) and Long Interspersed Nuclear Elements (LINEs).[3] These elements can be in two allelic states: either they are present in an individual's DNA as an insertion or absent as a null (INNULs). One advantage for targeting these markers is the small amplicon size that can be created for each marker (approximately 60bp-125bp in size).[4] A commercially available kit, InnoTyper™ 21, containing 20 INNUL markers plus the sex determining marker, Amelogenin, is available and was used for this study.4

The allele frequencies and population genetic parameters of the markers in a set of more than 600 population samples at National Institute of Standards and Technology (NIST) were characterized first.[5] Samples with close relatives (father/mother/child trios) were then genotyped for testing. Next, individuals in the trios were artificially degraded using sonication to generate fragmented DNA. Samples were typed with the INNUL markers and a commercially available multiplex STR kit for determining the Random Match Probability (RMP).

The utility of the INNUL markers for paternity and kinship analysis were considered. The software package LSAM-LISA Statistical Analysis Module from Future Technologies Inc. was used for direct comparison statistics and to conduct pedigree statistics for the INNULs. The program offered the ability to construct pedigree scenarios for kinship analysis. The software statistics were compared to those determined by hand calculation.

It was found that the INNUL markers were able to provide additional genetic information for samples that were highly degraded. The LSAM software program provided strong support for the concordance to produce accurate calculations for kinship analysis compared to hand calculation.

B143 Complex Mixtures and the Minimum Number of Contributors: A Case Study

Nathaniel D. Adams, BS, Wright State University, 3640 Colonel Glenn Highway, Dayton, OH 45435; Ranajit Chakraborty, PhD, University of N Texas Health Science Center, 3500 Camp Bowie Boulevard, Fort Worth, TX 76107; Carrie Rowland, MSc, Wright State University, 2850 Presidential Drive, Ste 160, Fairborn, OH 45324; and Dan Krane, PhD, 3640 Colonel Glenn Highway, Dept Bio Sci, Dayton, OH 45435*

After attending this presentation, attendees will better understand the challenges associated with estimating the number of contributors in a complex DNA mixture and the importance of making accurate assessments before attempting probabilistic genotyping to ascertain likelihood ratios. Results from an empirical analysis of simulated mixtures using real genotypes will be described.

This presentation will impact the forensic science community by: (1) illustrating the difficulties of assessing the number of contributors to a mixed sample; (2) presenting an exploration of novel empirical mixture analyses; and, (3) showing the impact these analyses have had on recent investigations involving probabilistic genotyping.

The scenario considered for this simulation study consists of a case in which a forensic DNA testing laboratory developed genotypes from three injections of DNA extracted from a swabbing of the grip area of a firearm found to be associated with a crime. The testing laboratory performed probabilistic genotyping analyses on the multiple injections, resulting in a single Likelihood Ratio (LR) reported for the swab of the grip area.

The calculation of LRs in forensic DNA statistics requires an explicit assumption of a number of contributors in both the numerator and denominator. Despite the observation of seven unique peaks at a single locus, the testing laboratory generated LRs under the assumption that only three individuals contributed to the observed DNA profile, suggesting that the single observation of a seventh peak at one locus across three injections was an artifact rather than an indication of a real allele and a fourth contributor. The final reported LR supported the data under H1 (Hp; Defendant + two unknowns) as being 4,190 times more probable than under H2 (Hd; three unknowns). The probabilistic genotyping system used for these analyses has not been validated for analyzing samples containing DNA from more than three individuals (as of June 2015). As a result, the testing laboratory was unable to evaluate the alternative hypotheses that four or more individuals contributed to the mixture.

An empirical analysis of 361 Caucasian genotypes published by the National Institute of Standards and Technology (NIST) indicates that of the 15 genetic loci genotyped by the commercially available Identifiler® test kit, approximately half of simulated, known, four-person mixtures (N=695,946,630) would have no more than six unique alleles observed at any locus. When disregarding the single locus with the highest count of unique alleles (as is the practice of the testing laboratory for this case) approximately 90% of all four-person mixtures would have no more than six unique alleles observed across the remaining loci. The results of this analysis indicate that the use of maximum allele counts for assessing the number of contributors is frequently inaccurate, especially for three or more contributors, and that an abundance of caution should be exercised when evaluating LRs in such instances.

The testing laboratory suggested that it was "more cautious" to consider the evidence sample to be a mixture of at least three individuals (presuming that allelic drop-in was likely to have occurred) rather than a mixture of at least four without providing any LR or level of confidence to that assertion. When confronted with these results and their implications, the testing laboratory and prosecution chose to withdraw their conclusions regarding DNA testing in this case prior to a judge's ruling in an admissibility hearing in a federal court.

Complex Mixtures, Number of Contributors, Likelihood Ratios

B144 A Single Multiplex Polymerase Chain Reaction (PCR) Assay of Rapidly Mutating (RM) Y-Chromosomal Short Tandem Repeat (Y-STR) Loci to Complement Current Sets of Markers Used in Forensic Y-Chromosome Analysis

Daniela Lacerenza, PhD, University of Torino, Dept Public Health Sciences, Sezione di Medicina Legale, c.so Galileo Galilei #22, Torino 10126, ITALY; Giancarlo Di Vella, MD, PhD, University of Torino, Dept Public Health Sciences, Sezione di Medicina Legale, Corso Galileo Galilei 22, Torino 10126, ITALY; and Carlo Robino, 22, Torino, TO 10126, ITALY*

The goal of this presentation is to introduce a set of RM Y-STR markers that can complement commercially available multiplex kits.

This presentation will impact the forensic science community by highlighting the ability of additional RM Y-STR loci to resolve paternal lineages and discriminate closely related male suspects.

Male-specific Y-STR loci are especially useful in cases of sexual assault, where mixed stains that contain abundant DNA from the female victim together with trace DNA from the male assailant are analyzed. A general drawback of Y-STRs is that, compared with autosomal STRs, their ability to identify single individuals is limited. Since mutation is the only driving force of variation in the human Y chromosome, and currently used Y-STRs have low mutation rates (in the order of 1 x 10-3), groups of paternally related men, and in particular closely related males, cannot be easily differentiated. To improve the power of discrimination of conventional Y-STRs, it is therefore necessary to complement them with additional markers with much higher mutation rates. Through a systematic study, it was possible to identify a subset of 13 RM Y-STRs displaying a few mutations per marker every 100 generations.[1] Part of these markers have subsequently been included in commercial kits such as the PowerPlex® Y23 system by Promega® (DYS570, DYS576) and Y Filer® Plus by Life Technologies™ (DYS570, DYS576, DYS627, DYS518, DYS449, and DYF387S1).

In a forensic context, minimization of analytical steps is necessary to draw as much information as possible from minute amounts of DNA isolated from stains; however, amplification of the RM Y-STR markers (DYF399S1, DYF403S1ab, DYF404S1, DYS526ab, DYS547, DYS612, and DYS626) not already included in the Y Filer® Plus panel, which currently represents the most comprehensive commercial set available for both conventional and RM Y-STR loci, was originally described in three separate reactions.[2] The goal of this project was to combine these reactions in a single compact multiplex PCR assay.

PCR primers and amplification conditions for the seven RM Y-STRs included in the multiplex are those described by Robino et al., with the exception of a modification of the dye label for locus DYS626 (from 6-FAM to TAMRA) in order to avoid overlapping between marker-specific fluorescent signals.[3] Developmental validation of the assay included a sensitive study of serial dilutions of male control DNA (2800M) and a mixture study, in which the serial dilutions of male DNA were mixed 1:1 with a female control DNA sample (200ng/µl).

The sensitivity study showed that full RM Y-STR profiles were obtained from as little as 62.5pg of template male DNA, whereas partial profiles, including drop-out artefacts at the multi-copy markers DYF399S1, DYF403S1a, and DYF404S1, could be observed at lower concentrations. Results were not affected by the concurrent presence of female DNA. Though the Y Filer® Plus panel has been shown to greatly improve the resolution of paternal lineages, it does not achieve complete differentiation, especially in more isolated/endogamous populations.[4] The described multiplex can therefore complement Y Filer® Plus data in selected cases requiring further power of discrimination, in particular when closely related male suspects are involved. The main concern regarding the use of additional RM Y-STRs in trace DNA analysis is that the occurrence of allelic drop-out and drop-in must be considered in multi-copy markers with a non-fixed number of alleles.

B145 Utility of InnoTyper™ 21 in Analysis of Degraded Human DNA Recovered From Maggot Crop Contents

Sharon E. Zeller, BS, 3940 Oakleys Lane, Richmond, VA 23223; Kyle S. Williams, Virginia Commonwealth University, 104 W Franklin Street, Apt 1703, Richmond, VA 23220; Sudhir K. Sinha, PhD, InnoGenomics Technologies, LLC, 1441 Canal Street, Ste 307, New Orleans, LA 70112; Gina M. Murphy, MS, GMP Forensic Consultants, PO Box 113006, Metairie, LA 70011-3006; Hiromi Brown, PhD, InnoGenomics, 1441 Canal Street, New Orleans, LA 70112; Daniel J. Wescott, PhD, Texas State University, Dept of Anthropology, 601 University Drive, San Marcos, TX 78666-4684; Tracey Dawson Cruz, PhD, Virginia Commonwealth University, 1015 Floyd Avenue, PO Box 843079, Richmond, VA 23284; and Baneshwar Singh, PhD*, Virginia Commonwealth University, Dept of Forensic Science, 1015 Floyd Avenue, Rm 2015, Richmond, VA 23284*

After attending this presentation, attendees will better understand the utility of a new human DNA typing method in nuclear DNA analyses of highly degraded samples (e.g., human DNA recovered from maggot crop contents).

This presentation will impact the forensic science community by providing a new, efficient, and alternate method for analysis of degraded human DNA recovered from maggot crop contents.

Blow flies and flesh flies are well-known for their utility in Postmortem Interval (PMI) estimation, but in some situations they can also provide information on relocation of a corpse, actual source of the maggot, identification of burned remains, and identification of a perpetrator in sexual assault cases.[1-3] This information can be obtained by recovery and analysis of human DNA from maggot crop contents, but recovered human DNA from maggot crop contents tends to be very degraded in a majority of cases. Hence, it generates either incomplete or a total lack of Short Tandem Repeat (STR) profiles.[4] This is primarily because traditional STR kits require longer target DNA fragments for the generation of complete STR profiles. To obtain more information from human nuclear DNA recovered from maggot crop contents, this study utilized InnoTyper™ 21, a novel DNA typing method. InnoTyper™ is a marker system that utilizes a 20 Retrotransposon Insertion Polymorphisms (RIPs) multiplex. Among the advantages of using RIPs are the following: (1) they do not yield stutter artifacts due to slippage during the PCR amplification; (2) there are no known genetic mutations since they are identical by descent only; (3) they are present in very high copy number; and, (4) they have a well-defined genetic lineage that makes them useful for relationship determinations. An innovative primer design allows for the amplicon size for the Alu markers to be reduced to a size (60bp-125bp) that is smaller then currently used STR markers, such that the substantially degraded DNA samples recovered from maggot crops can be analyzed.

To obtain a nuclear profile, DNA was extracted from crop contents of 20 third-instar larvae from two blow fly species (*Calliphora vicina* and *Lucilia sericata*), a positive control (i.e., frozen human liver tissue), a degraded control (30g of the human liver tissue placed under the same conditions as the test samples without exposure to maggots), and a negative control sample using QIAGEN® QIAamp® DNA Investigator kit. Extracted DNA was quantified using *Applied Biosystems® Quantifiler® HP and amplified for 20 RIP loci* and the gender-identifying marker, Amelogenin, using the amplification conditions and run parameters as recommended by the manufacturer. Capillary electrophoresis data were analyzed in GeneMapper® software V4.0.

On average, more than 48% of all alleles (202 out of 420 expected) were successfully recovered by this kit in maggot crops of both fly species. Human DNA recovered from some of the maggot samples actually yielded more complete profiles (90%-100% of all alleles were recovered) than the profiles obtained from the degraded control samples.

In conclusion, InnoTyper™ 21 has huge potential for its utility in the analysis of human DNA recovered from maggot crop contents.

InnoTyper™, Forensic, Maggot Crop

B146 Differentiation of Sand Grains From Different Locations Using Image Analysis and Multivariate Statistics

Jacob Hock, George Washington University, 2100 Foxhall Road, NW, Washington, DC 20052; and Walter F. Rowe, PhD, George Washington University, Department of Forensic Science, 2100 Foxhall Road, NW, Washington, DC 20007*

After attending this presentation, attendees will understand how to use photomicrography and image analysis coupled with multivariate statistics to compare and differentiate particulate samples from different locales.

This presentation will impact the forensic science community by showing how photomicrography and image analysis along with multivariate statistics can differentiate assemblages of particulate evidence from different sources.

Particulates appear as trace evidence in the investigations of a variety of crimes such as kidnapping, sexual assault, and homicide. Two questions are commonly asked of this type of evidence: (1) where could it have come from; and, (2) could it have come from a specific source? In the case of sand, investigators may want to know the type of environment (desert dune, river, or ocean) from which the sand came. If a crime scene or alibi location has been identified, investigators will inquire whether sand recovered from the clothing of a suspect or the suspect's vehicle could have come from that location. Laboratory examinations of sand samples commonly employ color determinations, X-ray diffraction, and polarized light microscopy to determine mineral content. Sizes, shapes, and textures of sand particles determined by light microscopy and scanning electron microscopy have been found to provide laboratory examiners with useful information about the environment from which the sand grains came.

The goal of this research was to determine if image analysis applied to photomicrographs of assemblages of sand grains could provide numerical estimates of the similarity or dissimilarity of pairs of sand specimens. Sand specimens were obtained from a variety of locations including deserts, rivers, lakes, and ocean beaches. Grab samples of sand grains were permanently mounted on microscope slides and photomicrographs of grains were captured with a 14-megapixel digital eyepiece camera. An open source image analysis program was used to process the images of the sand grains to obtain outlines of individual grains.

After much trial and error, it was determined that the best results were obtained using a mounting medium with a 1.54 refractive index and crossed polarizing filters. Because the sand samples were comprised primarily of quartz, the majority of the sand grains appeared bright against a black background. A montage of images was assembled for each sand sample and processed to obtain the values of a number of attributes of the sand grains, including area, perimeter, Feret diameters, circularity, aspect ratio, roundness, and solidity. Because many of these attributes are inter-correlated, Principal Component Analysis (PCA) was applied to the values of the grain attributes for pairs of sand samples. Factor plots for the first two extracted factors provided visual assessments of the similarity or dissimilarity the two sand samples. The extracted factors from the PCA were used to generate linear discriminant functions for assigning individual sand grains to their correct sample.

Preliminary results suggest that this approach can distinguish sand specimens from different locales. In particular, the desert sand specimen analyzed was very different from the two specimens from rivers, which in turn were different from a sand specimen from an ocean beach. Non-parametric tests (Kolmogorov-Smirnov, Mann-Whitney, and Kruskel-Wallace) were applied to the distributions of the discriminant values for the sand grains in each sample. For all pair-wise comparisons, the null hypothesis that the sand samples were drawn from the same population could be rejected at a confidence level greater than 95%.

These preliminary results demonstrate the potential of a simple, non-destructive method of analysis for the differentiation of particulate forensic evidence from different sources. The size and shape data derived from photomicrography can be combined for PCA with other numerical data, such as visible reflectance spectra and X-ray diffraction patterns for even greater differentiation of samples.

Polarized Light Microscopy, Image Analysis, Principal Component Analysis

B147 Development of Paper Microfluidic Devices for the Detection of Low-Explosives Residue

Kathryn R. Chabaud, BS, Florida International University, 11200 SW 8th Street, Miami, FL 33199; and Bruce R. McCord, PhD, Florida International University, Dept of Chemistry, University Park, Miami, FL 33199*

After attending this presentation, attendees will better understand current research on the development of paper microfluidic devices as a simple and inexpensive alternative to existing presumptive tests for low-explosives residues. Minimal training is required to operate these devices and they are ideal for use in the field by military and law enforcement entities. Attendees will also gain a basic understanding of the metallic components contained in low-explosive devices.

This presentation will impact the forensic science community by providing insight into the possibility of inexpensive, user-friendly, presumptive testing devices for low-explosive residues. This detector could be implemented in pre- and post-blast explosive detection and should be useful in screening unknown materials.

In this project, colorimetric tests are implemented on paper microfluidic devices, permitting metallic residues from low-explosive devices to be detected in the field. Paper microfluidic devices are typically prepared from chromatographic paper creating hydrophilic channels through the use of wax printing followed by lamination at elevated temperatures. Capillary action is then used to mobilize liquids containing dissolved analytes through the wax ink channels of the device. Colorimetric reagents are placed at the terminal end of each channel for detection of the individual analytes, which in this case are metallic salts. Paper-based microfluidic devices were initially designed for application in medicinal and disease testing in remote areas where the lack of refrigeration limits the ability to store expensive reagents. These devices now have a wide variety of applications. Because reagents are dried on the device prior to use, shelf lives are prolonged when compared to liquid reagents. Forensic applications of this technology have been explored. In this study, a paper microfluidic chip has been developed that involves presumptive, colorimetric tests for multiple, different metallic compounds contained in low-explosive residues. Colorimetric tests have been designed for a variety of these components. These tests were first prepared in solution and then optimized for use on paper.

Residue from flash powder-based explosive devices typically consists of inorganic salts resulting from the rapid deflagration of mixtures of inorganic oxidizers and metallic fuels. A paper microfluidic device for the detection of chlorate, perchlorate, and nitrate oxidizers was previously developed. As a follow-up, a paper microfluidic device for the detection of barium, aluminum, iron, and zinc fuels is being developed. Barium is detected via a buffered mixture of sodium rhodizonate, which yields an orange color upon reaction. Aluminum is confirmed via aluminon and ammonium acetate, which yields a pink/red color upon reaction. Iron is detected via p-aminophenol, which yields a purple color upon reaction. Lastly, zinc is detected with dithizone, which yields a bright pink/purple color upon reaction.

These devices are currently undergoing developmental validation to measure the reproducibility, stability, and sensitivity of the analysis. The paper-based devices should prove useful in the analysis of low-explosive residue as the chip is compact and minimal time is needed to produce results. The ultimate goal of the project is to design and test a series of these devices for the presumptive detection of a variety of explosives residues in the field.

Paper Microfluidics, Low Explosives, Colorimetric

B148 Crude Oil Characteristics for Identifying Petroleum Distillates in Fire Debris

Jeanet Hendrikse, MSc, Netherlands Forensic Institute, Laan van Ypenburg 6, The Hague 2497GB, NETHERLANDS*

After attending this presentation, attendees will understand which crude oil characteristics are necessary to distinguish petroleum distillates from non-conventional "petroleum-like" products in fire debris analysis results.

This presentation will impact the forensic science community by providing more detailed guidance in identifying and differentiating certain ignitable liquids products than can currently be found in scientific literature.

Petroleum distillates are crude oil refining fractions from the first refining process, the atmospheric distillation. These so called "straight-run" or "conventional" distillates are characterized by dominating alkanes and a relatively low content of aromatics. The composition of distillates generally mirrors the composition of the crude oil(s) from which it was distilled. The crude oil characteristics can therefore be used by fire debris experts for identifying petroleum distillates in fire debris and to distinguish them from: (1) distillates that have been further refined; and, (2) "petroleum-like" products that have been produced synthetically.

Straight-run distillates can be further refined for specific applications. Examples of processes are de-aromatization and de-waxing. De-aromatization is employed to remove or reduce the aromatic content; the alkane composition in this process remains unaffected. De-waxing is used to meet the low temperature properties required for its application. The end product of this process has no (or a reduced level of) n-alkanes and a branched alkane fingerprint pattern that no longer resembles that of crude oil. An alternative classification for these products, when encountered in fire debris analysis results, must therefore be considered.

Due to the imminent depletion of oil and the effect its usage has on the environment, more and more "petroleum-like" products are currently produced synthetically. Examples of such products are Gas-To-Liquid (GTL) diesel, some lamp oils, and some lighter fluids. GTL diesel is (and the other examples can be) the end product of the so called Fisher-Tropsch (FT) process. Some products, like lamp oils, are also currently known to be the blend result of a normal alkane product and an isoparaffinic product, the latter of which is obtained, for example, through an alkylation process.

Compared to petroleum distillates, these synthetic "petroleum-like" products do not contain a characteristic crude oil fingerprint pattern: branched alkanes are present but their pattern is different from that of crude oil, and both cycloalkanes, isoprenoïds, and aromatics (all present in crude oil) are absent. These synthetic "petroleum-like" products fall into the American Society for Testing and Materials (ASTM) E1618 class "Others-Miscellaneous."

The alkane pattern that is considered characteristic for straight-run petroleum distillates is discussed and illustrated in this presentation. Crude oil examples are illustrated to show that these characteristics originate from crude oil. Examples of more refined distillates and of synthetic "petroleum-like" products are illustrated to show that the alkane fingerprint pattern of these products does not resemble/no longer resembles that of crude oil.

Crude Oil, Characteristic, Petroleum Distillate

B149 Forensic Analysis of Textile Fibers Exposed to Laundry Detergents Using Fluorescence Excitation-Emission Spectroscopy

Nirvani Mujumdar, MS, 12029 Solon Drive, Apt 105, Orlando, FL 32826*

After attending this presentation, attendees will better understand forensic spectroscopy as a non-destructive analytical technique for forensic trace analysis.

This presentation will impact the forensic science community by demonstrating the usefulness of forensic spectroscopy as a non-destructive analytical technique for forensic trace analysis. This presentation will help attendees distinguish between fibers exposed to multiple launderings versus those that were never exposed. This study seeks to explain the effects of repetitive laundering on the total fluorescence of fibers and to determine the number of washes essential to make distinctions between washed and unwashed fibers.

Textile fibers are a major form of trace evidence, and the ability to reliably classify them is useful for forensic scientists. Before becoming an important source of evidence, fibers discovered at a crime scene are likely to be exposed to multiple launderings, which can possibly further add characteristic fluorescence components on the fibers. This can be a useful tool for the identification and analysis of forensic fiber evidence since detergents usually contain fluorescence whitening agents, which when accumulated on the fibers can modify the original spectral features of these fibers.

The primary goal of this project was to be able to distinguish between fibers exposed to multiple launderings versus those that were never exposed. Discovering common origins of trace evidential textile fibers can be a challenging task when fiber structure or dye composition does not provide exclusive identifying information. Introduction of new chemical species following mass production and distribution of a textile may be exploited to trace its history and identify the origin of its fibers.

In this presentation, a non-destructive technique known as fluorescence excitation-emission spectroscopy was used to examine the alteration in the fluorescence spectral fingerprint of single fibers resulting from exposure to commonly used detergents that contain fluorescent whitening agents. Seven top-selling detergents were used to wash fibers composed of diverse classes of dyes, colors, and compositions. Undyed acrylic, cotton, and nylon fabrics dyed respectively with basic green 4, direct blue 1, and acid yellow 17 dyes were laundered up to six times with the selected detergents, and the spectral contribution of each detergent onto single fibers was quantified and shown to reach a maximum after five sequential washes; however, in certain cases, some detergents even showed statistically meaningful differences to the fiber spectra after only a single wash. Fluorescence emission spectral profiles were collected and principle component cluster analysis was employed for additional statistical comparisons and differentiations, which facilitated to determine that the spectra of washed fibers were distinct from those of dyed, unwashed fibers. In the case of dyed nylon and cotton fibers, the laundered fibers were never misclassified as unwashed, but acrylic fibers showed very little detergent contribution to the fluorescence spectra.

Through this study, an attempt has been made to explain the effects of repetitive laundering on the total fluorescence of fibers and also to determine the number of washes essential to make distinctions between washed and unwashed fibers. Collection of a library of spectra from fibers washed zero to six times with popularly utilized detergents has enabled characterization of the spectral contribution of the detergent to the overall spectrum of the fiber, dye, and detergent. Lastly, these results indicate that washed and unwashed fibers were distinguishable with 95% accuracy.

Forensic Fiber Analysis, Fluorescence Spectroscopy, Laundry Detergents

B150 Investigative Predictions of Smokeless Powder Manufacturers

Dana-Marie K. Dennis, PhD, 5241 Millenia Boulevard, Apt 203, Orlando, FL 32839; Mary R. Williams, MS, National Center for Forensic Science, PO Box 162367, Orlando, FL 32816-2367; and Michael E. Sigman, PhD, University of Central Florida, National Center for Forensic Science, PO Box 162367, Orlando, FL 32816*

After attending this presentation, attendees will understand how the application of a Bayesian network to smokeless powder's physical and chemical characteristics data from a database can provide probability-based estimates of the manufacturer.

This presentation will impact the forensic science community by providing an investigative tool with the ability to predict the manufacturer of a smokeless powder based on its physical and chemical properties.

This research proposes the use of a Bayesian network that utilizes data from the National Center for Forensic Science (NCFS) and the Technical/Scientific Working Group for Fire and Explosions (T/SWGFEX) Smokeless Powders Database to suggest, by means of posterior probabilities, the manufacturer of a smokeless powder based on its physical and chemical characteristics. The dataset, comprising 119 NCFS smokeless powder database samples, contains information pertaining to the manufacturer, color, shape, average diameter, average length, and six class-associated ions which were previously determined from cluster analysis. Bayesian network structures are referred to as Directed Acyclic Graphs (DAG), which are comprised of nodes and arcs. Nodes represent events or variables which can have multiple states. Arcs represent causal dependencies between the nodes and are directed from parent nodes to child nodes. Probability tables are associated with each node; a parent node table encodes prior probabilities and child node tables encode class-conditional probabilities.

Two network designs have been explored. The first network contains a parent node representing the manufacturer of the smokeless powder with nine child nodes representing color, shape, m/z46, m/z120, m/z134, m/z149, m/z165, and m/z169. The second network is similar to the first, but has two additional child nodes representing the average diameter and average length of the smokeless powder. The m/z ions characterize the chemical composition of the smokeless powder; each one is a base ion for a specific compound or group of compounds. The networks were constructed and manufacturer posterior probabilities calculated using R statistical computing software. Prediction performance was estimated based on 100 iterations in which each repetition randomly withheld 5% of the dataset for testing; the remaining 95% was used to train the network. Values in the probability tables were calculated based on frequencies in the training dataset.

The networks were instantiated by entering evidence in the child nodes for each smokeless powder sample in the test set, and the prior probabilities in the manufacturer node were updated to posterior probabilities after the evidence was observed. The manufacturer for each test sample was predicted based on the highest posterior probability. Overall percent correct rates were determined by calculating the number of correct predictions; that is, where the known and predicted manufacturer were the same. The networks achieved overall percent correct rates of 66% and 70% for NET 1 and NET 2, respectively. The overall percent correct rates are significantly larger than the 20% random assignment rate. Work is continuing to focus on improving the overall percent correct based on posterior probabilities.

Smokeless Powders, Bayesian Networks, Database

B151 Modern Methodology for Explosives Tagging and Encoding Based on Luminescent Metal Organic Frameworks

Filipe Gabriel B. Mauricio, MSc, University of Brasilia, Instituto de Química - Campus Darcy Ribeiro, Brasília 70910-000, BRAZIL; Ingrid T. Weber, PhD, University of Brasilia, Instituto de Química -Campus Darcy Ribeiro, Caixa Postal 04478, Brasilia, Distrito Federal (DF) 70910-000, BRAZIL; Adauto Z. Pralon, MSc, Federal Police Departament, SAS Quadra 6, lotes 09/10 - ED.SEDE/DPF, Brasília 70037.900, BRAZIL; and Marcio Talhavini, PhD, Federal Police Departament, SAS Quadra 6, lotes 09/10 - ED.SEDE/DPF, Brasília 70910-000, BRAZIL*

After attending this presentation, attendees will understand methods of post-blast identification, collection of explosive residues by the addition of luminescent taggants, and the possibilities of encoding based on the metal ratio of the lanthanide ions by Energy Dispersive Spectroscopy (EDS) and typical light emission.

This presentation will impact the forensic science community by providing an easy, fast, and unequivocal method of identification/collection of explosive residues by the addition of luminescent taggants in commercial explosives that act not only as an optical probe, but that provide an encoding based on the metal ratio. The information provided by this presentation can be used to offer evidence that allows the identification of suspects in the criminal use of explosives.

During the past several years, Brazilian authorities have reported an increase in the number of attacks throughout the country on Automated Teller Machines (ATMs) with the use of explosives. According to the eighth edition of the national survey on bank attacks in Brazil, an increase of 147% was observed between the years 2011 and 2014.[1] Concomitantly, a growth of 38% in the cases of deaths by terrorist attacks has been observed around the world, in accordance with the Global Terrorism Index, in which 49% of these correspond to explosives attacks.[2] The evidence indicates the use of Ammonium Nitrate-Fuel Oil (ANFO) obtained from miners and carries in the attacks on ATMs in Brazil.[3]

Tracking and identifying suspects after explosions is one of the most challenging tasks in the forensic field. After detonation, most of the residue of the explosives is lost due to the volatility of the material, with the remaining trace residues being spread over a large debris field.[4] The growing criminal use of explosives has driven authorities to seek technologies that allow tracking of explosives. In 1973, Ryan et al. proposed to include a miscellany of metals and oxides as a way to encode explosives; luminescent materials were incorporated in these taggants in order to make the visualization and collection of residues easier for analysis.[5] Although good results have been obtained for the identification of residues, the need for including additives in explosive and encapsulating taggants was reported, which rendered the process less attractive.[6-9]

This work proposes a method to tag explosives by the direct addition of a luminescent Metal Organic Framework (MOF), which acts simultaneously as an optical probe (allowing easier visualization and collection of explosive residues) and as a chemical taggant (which tracks the explosive's origin). This research reports the use of two isostructural MOFs, (La0.8Tb0.2)(DPA)3(H2O)3 and (La1.6Eu0.2Tb0.2)(DPA)3(H2O)3, synthetized hydrothermally that emit orange and green light, respectively. The taggants were incorporated directly and manually into samples of ANFO explosives. Charges of 10g of tagged explosives were attached and detonated in computer cabinets simulating conventional ATMs.

Post-explosion residues were visually observed *in situ*, using only an Ultraviolet (UV) lamp (254nm). Afterward, the residues were collected and identified by luminescence spectroscopy and Energy Dispersive Spectroscopy (EDS). The EDS metal ratio of the explosives showed a high precision when compared with the pure samples that allowed an unequivocal coding method for each taggant. It was possible to not only observe the luminescent residues at the explosion scene, but the emitted color coupled to metal ratio also allowed for the unequivocal identification of the taggants. The methodology proved to be easy, fast, and very reliable.

B152 Do the Bulk Area and the Exterior Surface of Modern Container Glass Exhibit Differences in Refractive Index (RI) Measurements?

Joseph Insana, West Virginia University, Dept of Forensic and Investigative Science, 304 Oglebay Hall, PO Box 6121, Morgantown, WV 26506-6121; and Patrick Buzzini, PhD, Sam Houston State University, Chemistry/Forensic Science Bldg, 1003 Bowers Boulevard, Box 2525, Huntsville, TX 77314*

After attending this presentation, attendees will better understand the potential differences of RI measurements observed between external surfaces and bulk areas of glass containers. Attendees will also learn about the implementation of a simple and fast method to sample glass fragments from the surface of a glass object.

This presentation will impact the forensic science community, with emphasis to trace evidence examiners, by providing updated information on the potential RI differences that characterize the heterogeneity of this important optical property within modern container glass.

RI is known to be a highly discriminatory property used in forensic comparative examinations of glass. A critical aspect of RI measurements is the evaluation of intra-source variation. Indeed, RI is known to vary at different locations of a given glass object. In addition to spatial heterogeneity, previous studies indicate that differences in RI measurements could be observed between the external surface and the bulk area of a glass object. Considering the improvements of modern glass manufacturing processes, this study compares RI data from the external surfaces of glass containers to those collected from their bulk in order to determine if a significant difference exists.

The objectives of this study were: (1) the development of a method that separates the exterior surface from the internal bulk; (2) to produce representative RI data from the selected glass containers; and, (3) to apply a simple and robust statistic that informs about a potential difference between RI data from the bulk and exterior of a given glass container. This study intends to provide objective information to glass examiners concerned with the understanding of RI variation that could be expected between bulk and external surface for container glass. These results can be valuable when examiners interpret potential differences observed during comparative examinations or when they attempt to explain the dispersion of RI data as a consequence of a sampling method.

The body areas of eight glass containers were selected as initial samples for this study. These were two similar green beer bottles, two similar brown beer bottles, two similar green wine bottles, and two similar colorless honey pots. A novel methodology was developed to isolate the surface layer of glass fragments from their bulk. It consists of a simple and fast approach that scrapes fine glass debris from the surface of a glass fragment. Glass fragments were collected from the body area of the selected containers (as opposed to neck and base). A total of 560 measurements were taken using the traditional method for Glass Refractive Index Measurement based on the joint use of a hot stage and phase contrast microscopy. Fourteen fragments were selected for each container, seven from bulk and seven from exterior. Five RI measurements per fragment were taken for a total of 70 RI measurements per container. Data from the two areas were compared using the Welch version of the Student *t*-test (given the observed differences of variance between the two compared distributions). Differences between bulk and exterior were observed from the body areas of three glass containers out of eight. These differences were observed from glass objects of the same type and manufacturer.

Trace Evidence, Glass, Refractive Index

B153 Comparison of Cosmetic Foundations by Analysis of Preservative Content Using Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS)

Thomas A. Brettell, PhD, Cedar Crest College, 100 College Drive, Allentown, PA 18104; and Emily A. Myers, BS, 2133 Stoops Court, PO Box 602, North Apollo, PA 15673*

After attending this presentation, attendees will have a better understanding of how the analysis of preservatives can be used to compare cosmetic foundation samples submitted as trace evidence exemplars to forensic science laboratories.

This presentation will impact the forensic science community by providing a simple and sensitive LC/MS/MS method to compare cosmetic foundations by the analysis of a specific set of preservatives found in most cosmetic samples.

Preservatives are natural or synthetic ingredients that are commonly added to products in order to prevent spoilage, including but not limited to microbial growth or undesirable chemical changes, ultimately extending the product's shelf life. Without the addition of preservatives, the foundation has the ability to easily become contaminated, leading to product degradation and increasing the risk of irritation or infection. In the United States, the Food and Drug Administration regulates the use of preservatives under the cosmetic provisions of the law and requires manufacturers to determine at what levels the preservatives are considered "safe" for consumer use. The most widely used preservatives in cosmetic products are parabens.

This study developed an LC/MS/MS method for differentiating different brands of cosmetic foundations by observing the absence and or presence of specific preservatives, including six different parabens. The analyte preservatives used in this study were methylparaben, ethylparaben, n-propylparaben, isopropylparaben, butylparaben, benzylparaben, tocopheryl acetate, and 3,5-di-tert-butyl-4-hydroxytoluene (BHT). The method is capable of separating and identifying all eight preservatives in less than seven minutes including the separation of n-propylparaben and isopropylparaben, which has not been accomplished and reported prior to this method. LC/MS/MS data was acquired using an ABI® SCIEX™ 3200 QTRAP® triple quadrupole mass spectrometer interfaced with a Shimadzu® LC system. The instrument utilized Electrospray Ionization (ESI) and all samples were run in positive-ion mode monitoring. Chromatography was performed on a 5.0cm x 3.0mm x 2.7µm Ultra® biphenyl column. The strong mobile phase used was 0.1% formic acid in 2-propanol and the weak mobile phase used was 0.1% formic acid in High-Performance Liquid Chromatography (HPLC) -grade methanol. A Shimadzu® SIL-20AC Prominence auto sampler injected 2.0µL of sample and the column oven temperature was set isothermally at 25°C throughout the run with a flow rate of 0.300µL/min. A retention time optimization study provided preeminent separation conditions.

Foundation samples were prepared by adding 100mg of each foundation to 5mL of methanol:acetonitrile (1:1) and sonicating for ten minutes. After sonication, the solution was placed into centrifuge tubes and centrifuged for five minutes at 800G. After centrifugation, the supernatant was carefully removed using disposable pipettes and filtered using 0.2µm Millipore® filters. Then 1mL of the supernatant was added to a vial along with 60µL of the internal standard (BHA). Lastly, 2.0µL of sample was injected onto the LC column.

Separating and identifying the six parabens as well as the other preservatives proved to be simple and quick. The method is capable of identifying which preservatives are present in a cosmetic sample with a limit of detection of 0.5µg/mL. Twenty-six different brands of cosmetic foundations were tested and easily differentiated by analysis of the preservatives in the samples using the LC/MS/MS method.

Preservatives, Cosmetics, LC/MS/MS

B154 Development of a Sample Clean-Up Procedure for the Recovery of Trace Quantities of Organic Explosives in Soil and Sand

Erin Waddell, PhD, 2501 Investigation Parkway, Quantico, VA 22135; Jennifer Thomas, PhD, 3110 Spring Drive, Alexandria, VA 22306; Christopher C. Donnelly, 2121 Aquia Drive, Stafford, VA 22554; and Mark L. Miller, PhD, FBI Lab, CFSRU, 2501 Investigation Parkway, Quantico, VA 22135*

After attending this presentation, attendees will be informed about techniques for the extraction and detection of trace amounts of organic explosives residue from soil, sand, and oil-contaminated soil matrices utilizing Solid Phase Extraction (SPE).

This presentation will impact the forensic science community by providing an improved clean-up method for detecting trace organic explosives residue in complex matrices. In addition, this presentation will compare and contrast three SPE cartridges (Bond Elut NEXUS®, Empore™ SDB-XC, and Oasis® HLB) based on the recovery of organic explosives residue from soil/sand and matrix rejection.

The forensic science community is constantly searching to improve currently established protocols in lieu of older alternatives. A fast and simple option often used for samples is to use syringe filtration of the extract prior to sample analysis. Although samples are filtered, the sample typically contains matrix interferences that are not removed and are injected with the sample into the instrument. In this research, a Gas Chromatograph coupled to an Electron Capture Detector (GC/ECD) was utilized for analysis. The matrix of filtered samples may lead to signal suppression, increased background noise, and extra (or missing) peaks. If this occurs, instrument maintenance must be performed, which can be costly both in time and materials. The research to be presented focuses on finding an efficient extraction process that can separate the analyte(s) from the contaminants, facilitating sample throughput and reducing maintenance costs associated with instrument malfunction due to damage from matrix interferences.

Twelve organic explosives were investigated in this study: ethyleneglycol dinitrate (EGDN); dimethyl dinitrobutane (DMDNB); 4-nitrotoluene (4-NT); nitroglycerin (NG); 2,4-dinitrotoluene (DNT); 2,4,6-trinitrotoluene (TNT); pentaerythritol tetranitrate (PETN); trimethylene trinitramine (RDX); 2,4,6-trinitrophenylmethylnitramine (Tetryl); tetramethylene tetranitramine (HMX); erythritol tetranitrate (ETN); and cyclotrimethylene trinitrosoamine (R-salt). A mixture of these explosives was spiked onto samples of soil, sand, and soil contaminated with used motor oil. Acetonitrile was used to extract the explosives from the matrices. As a comparison of a simplified extraction procedure, syringe filtration was used prior to GC/ECD analysis for one sample set. This involved filtering the extracted liquid, a dry-down step to reduce sample volume, and injection via syringe for analysis by GC/ECD. In this research, the extraction liquid was cleaned up using Solid Phase Extraction (SPE) prior to GC/ECD analysis. This method has the advantage of bypassing the time-consuming dry-down step and of removing residual impurities contributed by the complex matrix.

In conclusion, the experiments reflected that it was possible to extract organic explosives residue from soil and sand samples using acetonitrile. Using SPE, it was possible to clean up the samples for GC/ECD analysis. Preliminary results indicate that the SPE cartridges provided the recovery of all 12 explosives, purified the oil-contaminated samples well, and generally did not require an extensive processing time. The results also indicate that the Oasis® HLB cartridges provided the highest percent recoveries of the explosives and are the most cost effective.

Explosives, Trace Analysis, Solid Phase Extraction

B155 Analysis of Inks Via a Microfluidics Extraction Device With a Quadrupole Time-of-Flight Mass Spectrometer (qTOF/MS)

Emily Lichtenberger, BS, North Carolina State University, 2401 Research Drive, Raleigh, NC 27606; and Nelson R. Vinueza, PhD, North Carolina Sate University, 2401 Research Drive, Campus Box 8301, Raleigh, NC 27695*

After attending this presentation, attendees will better understand a new Microfluidics Device (MFD) that can facilitate extraction of dyes, inks, etc. as well as a new understanding of analyzing inks from questioned documents via tandem mass spectrometry. Originally, the MFD was used for the extraction of dyes from fibers with minimal room for error because of the lack of contact between the examiner and the evidence.[1] Proven as a useful tool in previous work, the use of the MFD has expanded to analgesic tablet analysis and now to ink analysis from questioned documents, the main focus of this presentation.

This presentation will impact the forensic science community by providing a fast, accurate, and reproducible extraction and analysis methodology for a variety of evidences with minimal areas for human error and minimal damage to the evidence. For MFD Mass Spectrometric (MS) analysis, only a small amount of the evidence is needed, whether it is a single fiber a couple millimeters in length from a piece of fabric or a small microchip of the questioned document. This ensures that the majority of the evidence is preserved for court proceedings.

In these experiments, a variety of pens, markers, and highlighters in colors such as red, orange, yellow, and pink were analyzed using MFD-MS via Agilent® Technologies' 6520 quadrupole Time-of-Flight (qTOF). From previous work, it is known that Rhodamine 6G (Rh6G) and Rhodamine B (RhB) are common dyes found in writing utensils of these colors.[2,3] Both of these compounds were purchased from Sigma Aldrich® and used as standards for reference. The six writing utensils analyzed were obtained from a variety of manufacturers such as Sharpie® and Office Depot®. All experiments were completed at North Carolina State University in the analytical chemistry laboratory of the College of Textiles in Raleigh, NC.

Sample preparation consisted of drawing a single line to represent writing on a questioned document. A Harris Micro-Punch tool with a 2.0mm hole was used to take a micro-punch of the document. Due to markers having a larger amount of dispensed ink than pens such as ball point pens, only about a third of the micro-punch taken contained ink to ensure that saturation of the mass spectrometer detector would not occur, which indicates that more of the writing is preserved on the document. The micro-punch was then placed in the sample chip and inserted into the MFD. The extraction proceeded within the MFD using the program created in-house.[1] Acetonitrile (ACN) was flushed into the chamber of the cavity containing the micro-punch to extract the ink from the paper. This was done four times to ensure that extraction had occurred. Mass spectra were obtained via the qTOF mass spectrometer. The exact mass was identical for both Rh6G and RhB (443.2329); however, their structures differed and could be differentiated by their fragments when targeted via Tandem MS (MS/MS). RhB fragmentation included the loss of -CO2 which was observed by a fragment ion with m/z of 399; Rh6G fragmentation included the loss of -C2H4 which was observed by a fragment ion of m/z of 415.[3] This identification can be used to determine if one or both rhodamines are in the extracted ink. After each sample was analyzed, the MFD/MS system was flushed with Isopropyl Alcohol (IPA) until the ions of interest were low in abundance, and a blank sample was recorded to ensure that signals observed with the samples were from the extracted dyes. Total analysis and cleaning time per sample was estimated to be approximately 15-20 minutes depending on the user's knowledge of the system.

In conclusion, this analysis system in conjunction with the use of Rh6G and RhB as standards for red, orange, yellow, and pink writing utensils provides a new methodology to analyze questioned documents. Determination of whether the markers contained the rhodamines and, if so, which ones, have been successful and through repetition have shown that this technique is accurate and reproducible. Analysis time is decreased exponentially and minimal damage is done to the questioned document, ensuring that the majority of the evidence is conserved for later use.

B156 Gas Chromatography/Mass Spectrometry (GC/MS) Measurement of Gasoline Vapor Absorption on Clothing in a Confined Space

Charles R. Cornett, PhD, University of Wisconsin-Platteville, Dept of Chemistry, 1 University Plaza, Platteville, WI 53818; Sara C. Karp, BS, University of Wisconsin-Platteville, 845 S Chestnut Street, Apt 107W, Platteville, WI 53818; Ruth M. Henk, BS, Wisconsin State Crime Laboratory-Milwaukee, 1578 S 11th, Milwaukee, WI 53204; Kristy Stowe, BS, University of Wisconsin-Platteville, Dept of Chemistry, 1 University Plaza, Platteville, WI 53818; and Raymond G. Lenz, BS, Wisconsin State Crime Laboratory-Milwaukee, 1578 S 11th, Milwaukee, WI 53204*

After attending this presentation, attendees will better understand gasoline vapor absorption on cotton clothing in a confined space.

This presentation will impact the forensic science community by adding to the body of knowledge regarding the transfer of gasoline vapors to clothing in a confined space, information particularly important to the ignitable liquid/arson debris analysis community.

A recent case produced a question regarding the possible deposition of gasoline vapors on clothing as a suspect walked across a room in which the vapors were present. In the course of testimony, the defense council noted that gasoline was present on the defendant's footwear, yet there was no determination of gasoline on the defendant's clothing.

This research project focuses on the absorption of gasoline vapors by clothing in confined spaces. Research by Folkman et al., Coulson et al., and Errata et al. (under review) primarily deals with splashing or spilling of ignitable liquids onto clothing and the persistence of sufficient concentrations of ignitable liquids for identification.[1-3]

The experimental process was as follows. New, never-laundered, same-sourced cotton T-shirts were purchased along with new, one-gallon paint cans. An unventilated, steel, flammable 1.6m x 0.8m x 0.5m cabinet containing approximately 30L of 87-octane gasoline in standard one-gallon gasoline containers was used as the source of gasoline fumes. Vapors were allowed to accumulate in the cabinet for three months prior to the experiment. Samples were taken in triplicate of cotton T-shirts stored inside the cabinet for six hours, one hour, and fifteen minutes. In addition, one experimental condition measured the amount of absorbed gasoline vapor after 15 minutes of exposure followed by a one-hour ventilation in a fume hood. Subsequently, an additional experiment was performed on three T-shirts left hanging one meter from the open doors of the cabinet. Each T-shirt was placed in a clean, new, one-gallon paint can. An activated charcoal strip was suspended in the can, which was then heated at 70°C for 16 hours. The activated charcoal strips were washed with carbon disulfide and analyzed by GC/MS.

Results of the experiment show detectable amounts of gasoline (BET, alkylbenzenes, and naphthalenes) for the T-shirts exposed to gasoline vapors in the cabinet for periods of six hours and one hour; however, even in the extremely confined and unventilated space, the T-shirts exposed for 15 minutes did not display sufficient naphthalene concentrations for an identification, even prior to the one-hour, in-hood ventilation. The conclusion is that the necessary concentration for gasoline vapors to absorb into cotton T-shirts and be detected would likely lead to the incapacitation or death of the individual wearing the clothing.[4] The absorption and persistence of solely gasoline vapors onto cotton clothing of a suspect who has left the crime scene appears very unlikely according to the results of these experiments.

Gasoline, Ignitable Liquid, Clothing

B157 Observations on the Incidence of Transfer of Fibers to Knives During Penetration Cuts

Barbara Doupe, MSc, Centre of Forensic Sciences, 25 Morton Shulman Avenue, Toronto, ON M3M 0B1, CANADA; Vanessa Londero, BSc, University of Ontario Institute of Technology, 2000 Simcoe Street, N, Oshawa, ON L1H 7K4, CANADA; and Cecilia Hageman, PhD, University of Ontario Institute of Technology, 2000 Simcoe Street, N, Faculty of Science, Oshawa, ON L1H 7K4, CANADA*

After attending this presentation, attendees will have a better understanding of fiber transfer to knives during stabbings through clothing. Possible correlations were examined between the number of fibers transferred and their location on a knife blade versus the blade type, number of penetrations, direction of penetration, fabric construction, and fiber composition.

This presentation will impact the forensic science community by dispelling misconceptions about fiber transfer onto knife blades during stabbing incidents. This includes the expectation that serrated blades are significantly more prone to entrain and retain fibers than straight blades and that the fiber composition and/or fabric construction would significantly affect the number of fibers transferred. Fibers transferred to a knife blade can be critical evidence when the knife is recovered in a different location from the complainant and DNA is not probative to the case. While previous studies address the force required for a knife to penetrate a model of a clothed body or the fabric damage caused, there have not been previous studies looking at either the transfer of fibers to a knife during stabbing nor the variables that may impact the number and location of transferred fibers.

Pork shoulders were used as the knife penetration substrate. They were covered with four different types of fabric to mimic clothing: cotton-woven denim fabric, cotton jersey knit fabric, polyester tricot knit fabric, and polyester-woven windbreaker fabric. Single and double penetrations were made aligning the knife blade with the lengthwise direction, the crosswise direction, or on a diagonal of the fabric. The penetration cuts were made using either a serrated blade or a straight blade. Each sequence of variables was repeated three times for a total of 144 penetrations. After each penetration, the fibers transferred to the blade were collected and counted.

The average number of fibers collected after single penetrations with the serrated blade and with the straight blade were, respectively, 98 and 86 for the cotton denim fabric, 92 and 32 for the cotton jersey knit fabric, 80 and 105 for the polyester tricot knit fabric, and 54 and 29 for the polyester windbreaker fabric. These fibers were most frequently observed along the cutting edge and along the deepest point of penetration on both types of blades.

The average number of fibers collected after double penetration with the serrated blade and with the straight blade were, respectively, 102 and 80 for the cotton denim fabric, 72 and 63 for the cotton jersey knit fabric, 37 and 76 for the polyester tricot knit fabric, and 69 and 38 for the polyester windbreaker fabric. These fibers were most frequently observed along the deepest point of penetration after the double penetrations on the straight blade; however, this was not always the case for the serrated blade.

Significant numbers of fibers were transferred to the blades along the cutting edge and at the deepest point of penetration of the blade during penetration. Correlations were not observed between the number of fibers transferred, or their location on the blade, with blade type, number of penetrations, direction of penetration, fabric construction, or fiber composition. The expectation that more fibers would be transferred to a serrated knife was not supported by the observations.

Fiber, Transfer, Knife Cuts

B158 Low-Cost Lanthanide-Organic Framework Markers for Gunshot Residue (GSR) Identification

Isabela Bastos Serwy, SQN 305 Bl C Ap 305 Asa Norte Brasília DF, Brasília, Distrito Federal 70737060, BRAZIL; Kaline Wanderley, PhD, Chemistry Institute, University of Brasília, 709, Brasília, BRAZIL; Marcella Auxiliadora de Melo Lucena, MS*, Rua Capitão José Nogueira Costa, 46, Várzea, Recife, Pernambuco 50810-270, BRAZIL; Marcio Talhavini, PhD, Federal Police Departament, SAS Quadra 6, lotes 09/10 - ED.SEDE/DPF, Brasília 70910-000, BRAZIL; Marcelo O. Roderigues, PhD, LIMA, Chemistry Institute, University of Brasília, Brasília, BRAZIL; and Ingrid T. Weber, PhD*, University of Brasilia, Instituto de Química - Campus Darcy Ribeiro, Caixa Postal 04478, Brasilia, Distrito Federal (DF) 70910-000, BRAZIL*

After attending this presentation, attendees will better understand the new types of low-cost markers for non-toxic ammunition using luminescent materials, which simplify the investigative routines but also allow the use of the characterization method already used for conventional munitions.

This presentation will impact the forensic science community by adding to research by providing the synthesis of a new type of luminescent markers for GSR based on the Metal-Organic Framework (MOF) [Zn(BDC)(H2O)2]n doped with the lanthanide ions terbium and europium, by a simple, fast, and reliable methodology with low-cost production.

GSRs are an important source of information in forensic analysis; however, with the advent of Non-Toxic Ammunition (NTA), also known as lead-free ammunition, the characterization of GSR became a very difficult task since GSR produced by NTA does not contain any characteristic elements (for example, Pb, Sb, and Ba) that allow unequivocal characterization. Thus, the standard methodology for GSR characterization adopted by the American Society for Testing and Materials (ASTM) International based on Scanning Electron Microscopy coupled to Energy Dispersive Spectroscopy (SEM/EDS) becomes inadequate. In this context, luminescent ammunition markers were developed. These markers allowed the visual identification of the Luminescent GSR (LGSR) on the shooters' hands, the firearm, and at a simulated crime scene using only an Ultraviolet (UV) lamp. It provides a simple, fast, and reliable methodology that improves the crime scene investigation.[1-3]

Among many materials tested as possible markers, the MOFs containing lanthanide ions were shown to have a large potential to be used as GSR markers due to their high luminescence and high chemical and thermal stability. Excellent results were obtained with lanthanide-based MOFs; however, in general lanthanide-based materials are relatively expensive.[2,3] On the other hand, the cost of the markers can be reduced by using d-metal-based MOFs doped with lanthanides. Thus, in this work, the coordination network [Zn(BDC)(H2O)2]n doped with different proportions (0.01% to 100%) of Tb^{3+} or Eu^{3+} evaluated as GSR luminescent markers. The materials were synthetized at room temperature by direct precipitation reaction and incorporated into the gunpowder of 9mm CleanRange® NTA cartridges in a ratio weight of 4%. Then, for each marker, three shots were performed using Glock® G17 pistols at the indoor shooting range in the ballistics service of the National Institute of Criminalistics of the Brazilian Federal Police (NIC/BFP). Next, LGSR particles were visualized on the firearm, the shooter's hands, and the target when MOFs containing more than 1% of lanthanide were used. The best results were obtained when 10% of Tb^{3+} or Eu^{3+} were incorporated into the MOF. Finally, the LGSR were collected with stubs covered with double-sided adhesive conductive carbon tape and analyzed by SEM/EDS and by video spectral comparator (where emission spectra were acquired).

The emission spectra of LGSR showed the characteristic transitions $^5D_4 \rightarrow {}^7F_J$ (J=3-6) of Tb^{+3} and $^5D_0 \rightarrow {}^7F_J$ (J=0-4) of Eu^{+3}, with the most intense the transitions at 543nm and 614nm (responsible for the green and red emission colors of these markers, respectively). Additionally, the EDS spectra confirmed the concomitant presence of the zinc and Tb or Eu ions in the LGSR, showing that in addition to the optical signature, the markers confer a chemical signature to ammunition. $[Zn(BDC)(H_2O)_2]n$: Tb or Eu presents an interesting effective cost, being up to eight times less expensive than the fully lanthanide-based marker.

B159 Characterization of Hair Dyes Using Ultra High-Performance Liquid Chromatography Electrospray Ionization Time-of-Flight Mass Spectrometry (UHPLC-ESI-TOF/MS) for the Forensic Analysis of Dyed Hair

Diana I. Camacho, 3819 S Honore, Chicago, IL 60609; Ira S. Lurie, PhD, George Washington University, Dept of Forensic Science, 2100 Foxhall Road, NW, Somers Hall, Lower Level, Washington, DC 20007; and Ioan Marginean, PhD, George Washington University, 2100 Foxhall Road, NW, Somers Hall L14C, Washington, DC 20007*

After attending this presentation, attendees will learn about the process and chemicals used to dye human hair and options for analysis of dyed hair. The attendees will be exposed to the idea of using HPLC with MS detection to analyze dyed hair for forensic purposes.

The presentation will impact the forensic science community by suggesting a technique that brings additional support to hair evidence when an association can be made between a person and the crime scene based on dyed hair. This technique involves dye extraction from hair using typical solvents followed by LC analysis with MS detection.

Forensic analysis of questioned hair typically entails microscopic comparison with known hair collected from the suspect or from the victim possibly followed by mitochondrial DNA analysis if the investigation microscopic comparison does not result in an exclusion. The microscopic comparison is a quick yet notoriously unreliable technique, which requires an extremely well-trained investigator. Many convictions obtained using hair evidence were later reversed based on DNA evidence, emphasizing an unacceptable rate of false positives.

Mitochondrial DNA analysis can reduce the probability of false positives to a very low, yet still unacceptable, value. Unlike nuclear DNA analysis, mitochondrial DNA analysis cannot individualize the evidence to a single suspect/victim with sufficient confidence. When both the questioned and the known hairs were dyed, the analysis of hair color can further increase the evidentiary power of hair. This is especially important when any other type of evidence linking the victim/suspect to the crime scene is missing.

Eighty percent of commercial hair formulations are permanent, oxidative dyes. They consist of a mixture of small precursors known as primary intermediates and coupling molecules that enter the hair fiber and react under oxidative conditions to form larger dye molecules. The size of the dyes prevents them from leaving the hair and they become deposited in the hair cortex to produce long-lasting color. Booster dyes are sometimes added to commercial formulations to tune the resulting hair color. Depending on the composition of the precursors and their relative amounts in a dye kit, different hair colors can be achieved.

This study seeks to examine, characterize, and identify dyes extracted from human hair via instrumental analysis for the purpose of determining common origin. UHPLC-ESI-TOF/MS was used to identify the components of permanent hair dyes. A UHPLC separation of dyed hair sample extracts was indicative of a small collection of predicted oxidation dye products, though with very low intensities. Dyes formed from oxidation reactions are more difficult to extract and detect than additive or booster dyes found in the same dye kit. Dye signals can vary in intensity among different permanent dye formulations of similar colors, even when they contain similar precursor molecules. Extraction method studies determined the heated methanol extraction procedure provided better extraction of oxidation dyes than a sodium hydroxide hair digestion. It was also determined that there is no direct correlation between the length of a hair sample and the intensity of detected dyes, limiting the forensic value of quantitative dye measurements.

Hair, Liquid Chromatography, Mass Spectrometry

B160 Analysis of Change in Nitrite-to-Nitrate Ratios in Gunshot Residue Over Time Using Ion Pairing High-Performance Liquid Chromatography (HPLC)

Anusha Rankoth, 100 College Drive, Allentown, PA 18104; Marianne E. Staretz, PhD, Cedar Crest College, Dept of Chemical & Physical Sc, 100 College Drive, Allentown, PA 18104; Peter J. Diaczuk, BS, 445 W 59th Street, New York, NY 10019-2925; Thomas H. Pritchett, MS, 100 College Drive, Allentown, PA 18104; and Elana Conant, MS, Cedar Crest College, 100 College Drive, Miller #10, Allentown, PA 18104*

After attending this presentation, attendees will be familiar with an ion-pairing HPLC method for measuring nitrate and nitrite that can be a useful analytical tool in Gunshot Residue (GSR) analysis.

This presentation will impact the forensic science community by introducing an HPLC method that can measure the levels of nitrate and nitrite in GSR in the barrel of a firearm. This method has the potential to determine the time frame in which a firearm was last discharged.

There is a high level of nitrites and nitrates present in GSR due to the high nitrogen content of the propellant used in smokeless powder cartridges. After discharge, these components are left behind within and on the firearm. Given that nitrite oxidizes to nitrate, it is feasible to assume that the nitrate-to-nitrite ratios within the gun barrel residue will change with time. Therefore, a gun that was fired several days prior might be expected to have a lower nitrite-to-nitrate ratio than a gun that was fired more recently; however, because different ammunition manufacturers use different ingredients when constructing their cartridges, these ratios may differ among various ammunition types.

This study has developed an HPLC method which can be utilized to measure the nitrite-to-nitrate ratios within the barrel of a firearm after it has been discharged and can determine if there is any change in this ratio over time that may prove useful for estimating the time frame in which this discharge occurred. This method consisted of an ion-pairing system using the ion-pairing agent tetrabutylammoniumhydrogen sulfate. Successful separation of the target analytes is possible in less than five minutes. The HPLC data was collected using an Agilent® 1100 HPLC system. The system utilized a diode array detector and absorbance was monitored at 205nm. Separation was accomplished using a 100mm x 2.1mm x 2.6µm Kinetex® C_{18} column. The mobile phase consisted of 95% 10mM tetrabutylammonium hydrogen sulfate in a 2.0mM sodium phosphate buffer adjusted to a pH of 8.4 and 5% HPLC-grade acetonitrile. Quantitation of nitrite-to-nitrate ratios was completed by analyzing the respective peak area via Agilent® Chemstation. Sample injections of 20µL were made using an autosampler at a flow rate of 0.20ml/min.

Gunpowder (smokeless powder) was burned in the open and samples were collected at various time intervals using Absorbond® polyester swabs dampened with HPLC-grade water. The swabs were then placed into 2ml of mobile phase. Extraction was carried out for 10-15 minutes followed by filtration using 0.2µm syringe filters. Filtered samples were placed into autosampler vials for analysis.

The retention time of nitrite present in GSR using this method is 2.4-2.5 minutes. The retention time for nitrate in GSR samples is 3.9-4.0 minutes. Starting ratios of nitrite to nitrate at time zero range from 1 to 0.92. After 24 hours, the ratios decreased to a range of 0.45 to 0.49. After an additional 24 hours, the ratios decreased again to approximately 0.27. These results indicate that nitrite-to-nitrate ratios decrease approximately 50% over a 24-hour period. With this type of data, it may be possible to construct a calibration curve which will be an important tool in determining the approximate time a firearm was last discharged.

Separation of nitrite and nitrate using this isocratic ion pairing system proved to be swift and reliable. The method was applied to the analysis of gunpowder residue. The oxidation of nitrite to nitrate in the sample was confirmed using this method. It was also confirmed that the nitrite/nitrate ratios decreased over time. This method will be utilized to analyze GSR in the barrel of a firearm at various time intervals after firing. These results will also be presented.

Gunshot Residue, HPLC, Ion Pairing Chromatography

B161 Evaluation and Validation of a Model to Quantify the Weight of Fingerprint Evidence

Henry J. Swofford, MSFS, 4930 N 31st Street, Forest Park, GA 30297; Anthony Koertner, 4930 N 31st Street, Forest Park, GA 30297; and Michael J. Salyards, PhD, 45 High Street, Sharpsburg, GA 30277*

The goal of this presentation is to introduce attendees to a novel method for quantifying the weight of fingerprint evidence, which has been developed and is currently undergoing validation by the United States Army Criminal Investigation Laboratory. After attending this presentation, attendees will have a better understanding of the difficulties with supporting claims of single-source attribution (e.g., "individualization") and be introduced to an alternative framework implemented within the Department of Defense.

This presentation will impact the forensic science community by helping attendees better understand the mathematical concepts by which this method was developed, the results of preliminary evaluation data against mated and non-mated fingerprints obtained from a database of several million fingerprints, and the on-going validation efforts to facilitate the transition of this technology into practice. This presentation will explore the evolution of fingerprint testimony, highlight potential issues with the current reporting paradigm, and recommend an alternative reporting framework to ensure fingerprint results are reported in an epistemologically compatible and more scientifically defensible manner.

For more than 100 years, fingerprint evidence has been used as a valuable tool for the criminal justice system. Relying on the generalized premise of "uniqueness," the forensic and legal communities have regarded fingerprint evidence as nearly infallible, having the capacity to "individualize" the source of a fingerprint impression to a single individual. While the uniqueness of a complete record of friction ridge skin detail is generally undisputed, the extension of that premise to partial and degraded impressions has become a central issue of debate. As a result, the traditional paradigm of reporting latent fingerprint conclusions with absolute certainty to a single source has been challenged. The underlying basis for the challenge pertains to the mathematical logic applied and the manner in which the evidence is articulated. By recognizing the subtle yet non-trivial differences in the mathematical logic, the fingerprint community may consider an alternative framework to report fingerprint evidence to ensure the certainties are not over- or understated. This presentation will discuss the logic largely subscribed to by the fingerprint community along with the underlying basis to why it is the focus of challenge, present an alternative framework for the community to consider adopting which is epistemologically more compatible and defensible, and discuss how this transition was achieved within the Department of Defense without minimizing the value of fingerprint evidence.

The opinions or assertions contained herein are the private views of the authors and are not to be construed as official or as reflecting the views of the United States Department of the Army or United States Department of Defense.

Fingerprints, Likelihood, Statistics

B162 I Know It When I See It — Is Complexity the Key to Creating a Workable Documentation Policy for the Pattern Evidence Disciplines?

Heidi Eldridge, MS, RTI International, 3040 E Cornwallis Road, RTP, NC 27709*

After attending this presentation, attendees will be able to articulate the main arguments in favor of the creation of policies requiring contemporaneous documentation of the basis for conclusions in the pattern evidence disciplines. Preliminary data will illustrate how consensus complexity determinations can be used to design an operationally reasonable policy, using latent prints as a model system. Attendees will also be able to describe the challenges in defining complexity in highly interpretive disciplines. Finally, attendees will be equipped with practical suggestions on how to design and implement such policies in their own laboratories.

This presentation will impact the forensic science community by frankly discussing the need for documentation in the pattern comparison disciplines, then by providing a roadmap for designing and implementing a policy that meets those needs without being overly cumbersome operationally. This presentation will present data from multiple exercises to achieve this goal and provide suggestions for moving forward in light of these data.

The pattern evidence comparison disciplines (e.g., latent prints, handwriting, firearms and tool marks, and footwear and tire marks) are highly interpretive in nature. When there is a high level of human interpretation involved, variability inevitably follows. This variability can lead to a host of issues, notably inconsistency in conclusions and difficulty in demonstrating reliability. Without documentation of the basis for a conclusion, it is difficult to resolve these issues.

If two examiners disagree on a conclusion, they have no way to articulate the reasons behind their differing conclusions without documentation as to how they reached those conclusions. If an error is discovered (typically months or years after the fact), there is no way to perform a root cause analysis if there was no documentation made of how the incorrect conclusion was reached. Without documentation, there is no way to assess the validity of a conclusion, whether that assessment is being made by a reviewer, an opposing expert, or a trier of fact.

In trying to develop a documentation policy, the first instinct of many laboratories is to base the policy on the complexity of the unknown image — a poor quality image requires more documentation than a pristine one; however, there are challenges in taking this approach. “Complex” is a term that has not been well-defined and the complexity threshold itself is subject to a level of variation between practitioners.

Using latent prints as a model system, exercises were created and executed in order to identify and isolate the components of complexity and create a process by which consensus on image complexity could be reached, such that a documentation policy could be built around it. This study presents the results of that effort, along with a description of the process, a roadmap for repeating the process in any laboratory, and suggestions for practical documentation policies that will achieve the goals of documentation without being too operationally cumbersome.

The National Institute of Justice (NIJ) Forensic Technology Center of Excellence (FTCoE) is committed to improving the practice of forensic science and strengthening its impact to agencies dedicated to combating crime. This FTCoE presentation recognizes the importance of balancing the implementation of best practices with recognizing the operational needs of a functional forensic science laboratory.

Documentation, Pattern Evidence, SOPs

B163 A Bibliometric Review of the Impact of the National Academy of Sciences (NAS) Report on the Friction Ridge Discipline

Maria A. Roberts, 2501 Investigation Parkway, Quantico, VA 22135; Kathryn B. Knorr, MS, 2501 Investigation Parkway, Quantico, VA 22135; and Kyle Tom, MS, 2501 Investigation Parkway, Quantico, VA 22135*

After attending this presentation, attendees will better understand the transition friction ridge research made after the National Research Council on the 2009 NAS Report, Strengthening Forensic Science in the United States: A Path Forward, was published.

This presentation will impact the forensic science community by comparing research trends in the friction ridge discipline both pre-NAS Report and post-NAS Report. A bibliometric review will be contrasted against an informal review of the literature considered important by Subject Matter Experts (SMEs) in the friction ridge discipline.

The impact of the NAS Report on friction ridge literature was measured in a bibliometric review by using an online literature indexing tool, Web of Science™, and focusing on the five years before and after the NAS Report. This bibliometric review showed an increase in the number of friction ridge articles indexed in Web of Science™ from an average of 22.6 articles per year between 2005 and 2009 and an average of 41 articles per year between 2010 and 2014. The predominant funding agencies also changed: the National Institute of Justice, Federal Bureau of Investigation, and the Home Office (United Kingdom) became the top three contributors post-NAS Report, but none of them were in the top three pre-NAS reports. Four of the five most prolific authors remained in the top five between both time frames, and all five countries remained in the top five.

A search of common terms associated with fingerprints produced an overwhelming amount of unassociated articles since the term "fingerprint" is used outside the friction ridge discipline. Web of Science™ lacks a specific forensic science category, so several categories were selected to focus on the appropriate articles; however, this lack of specificity required an additional manual screening process to remove articles that were visibly not associated with the friction ridge discipline. Sensitivity of a bibliometric review is reduced due to limiting the search on specific categories, as well as not containing journals that are not indexed.

Using bibliometric tools to review literature has its limitations, such as relying heavily on key words, a lack of a specific forensic science category, and partial lists of indexed journals. The methods, though, are objective, and the results can be quantified. This broad, calculated, and repeatable approach of a bibliometric review was contrasted to a more concise, influential, but subjective list of articles that was organically produced by the friction ridge discipline in response to the NAS Report.

B164 Fingerprint Aging Mechanism Determination Through Electrochemistry

Roberto Rosa, PhD, University of Modena and Reggio Emilia, Via Pietro Vivarelli 10, Modena 41125, ITALY; Roberto Giovanardi, PhD, University of Modena and Reggio Emilia, Dept of Engineering Enzo Ferrari, Via Pietro Vivarelli 10, Modena 41125, ITALY; Andrea Bozza, MSc, University of Modena and Reggio Emilia, Dept of Engineering Enzo Ferrari, Via Pietro Vivarelli 10, Modena 41125, ITALY; Paolo Veronesi, PhD, Dept Materials and Environmental Engineering, via Vignolese 905, Modena 41125, ITALY; and Cristina Leonelli, PhD, Dept Materials and Environmental Engineering, via Vignolese 905, Modena 41125, ITALY*

After attending this presentation, attendees will understand the great potentialities offered by electrochemical techniques in the fascinating and highly challenging research field of fingerprint age determination. Currently, a reliable, quantitative, and reproducible technique for determining the age of fingerprints found at the crime scene is still lacking, although it is considered one of the major challenges for future forensic science innovation.[1,2]

This presentation will impact the forensic science community by demonstrating a quantitative determination of the fingerprint aging mechanism through Electrochemical Impedance Spectroscopy (EIS) measurements. Prior to a reliable method for fingerprint age determination being effectively developed, a deeper understanding of the aging mechanism is necessary as research efforts must be refocused on the fundamental understanding of the fingerprint itself.[3]

This study seeks to accurately investigate the fingerprint aging mechanism on selected metallic substrates, namely AISI316L stainless steel, aluminum (6082), and brass. The chemical as well as the physical modifications which a fingerprint undergoes over time will surely affect the electrochemical response of the system, constituted by the print residue and the substrate on which it has been deposited.

As recently recommended by the International Fingerprint Research Group (IFRG), natural "ungroomed" marks were tested in order to evaluate the proposed technique for actual scenarios.[4] A three-electrode cell was employed for the EIS measurements, using the metallic substrate bearing the fingerprint as the working electrode, a platinum foil as the counter electrode, and $Ag/AgCl/KCl_{sat}$ as the reference electrode. The impedance spectra were acquired in the 100kHz÷100mHz frequency range (ω), applying a sinusoidal potential wave (0V bias, 10mVrms of amplitude). In this way fingerprints were monitored over a time period of 45 days.

The equivalent circuit used to fit the experimental impedance data collected at different aging times was a Randle's one R(QR), consisting of an ohmic resistance, mainly ascribed to electrolyte (i.e., 0.2 M Na2SO4) solution, in series with the parallel combination of the double-layer capacitance (C_{dl}) and the charge transfer resistance (R_{ct}) of the reaction activated during the slight polarization applied to the substrate. The double-layer arrangement of the systems investigated in this study differs from an ideal capacitor, thus a Constant Phase Element (CPE) whose impedance contribution is reported in Equation 1 has been used to replace C_{dl}.

Equation 1: $Z(w)=Y_0(jw)^{-n}$. Y_0 represents a constant with dimension $F\times s^{n-1}$, ω is the applied frequency, while j=Ö-1and $0<n<1$. The EIS results showed that the fingerprint mainly affects the capacitance of the double layer formed at the metal substrate/electrolyte interface: the fingerprint aging process has, as its main effect, a decrease of the active area of the metal substrate (due to the spreading of the fingerprint on the metal surface), a phenomenon which leads to a decrease of the capacitance of the electric double layer, directly correlated with the ageing process, through a 3-parameters exponential decay equation of the type in Equation 2.

Equation 2: $y=y_0+ae^{-bx}$. Similarly to what observed for the Y_0, the exponent n reported in Equation 2 also undergoes an exponential decay during the aging of the fingerprint. This latter behavior can be correlated to a variation in the roughness of the fingerprint-substrate system, in accordance to literature data.[5] On the contrary, the R_{ct} value does not significantly change during the aging process: this result suggests that the only faradaic reaction activated during the slight polarization applied to the substrate is the oxidation of the metallic substrate (hypothesis confirmed by the high R_{ct} values obtained, which are consistent with the passive behavior of the metals used when exposed to the selected electrolyte).

In conclusion, EIS allowed this study, for the first time, to quantitatively clarify the aging mechanism of fingerprints on metallic substrates, smoothing the way for reliable fingerprint age determination studies and for considering the possibility of easily coupling EIS to further electrochemical-based techniques (this latter aspect being the main focus of current research).

B165 Performance and Ricochet Characteristics of Frangible Ammunition

Peter J. Diaczuk, BS, 445 W 59th Street, New York, NY 10019-2925; Jack Hietpas, PhD, FBI-ORISE, 2501 Investigation Parkway, Quantico, VA 22135; and Xiao Shan Law, BS, 1937 W 6th Street, Apt 2R, Brooklyn, NY 11223*

After attending this presentation, attendees will understand the difference between conventional ammunition and frangible ammunition. Attendees will also become familiar with several types of frangible ammunition, whether these types of frangible bullets acquire individual markings after being fired, and how some break apart into fragments that bear little resemblance to a bullet if found at a shooting scene.

This presentation will impact the forensic science community by exploring the components of the frangible ammunition obtained for the study, how they behave upon impact, and whether fired bullets are amenable to comparison microscopy.

Frangible ammunition is constructed in a similar fashion to conventional ammunition regarding the cartridge case, the primer, and the propellant, but that's where the similarity ends. Conventional bullets, often consisting of a dense lead core either fully or partially enclosed with a harder copper jacket, or even unjacketed, can remain intact after a ricochet or after perforating a barrier. Ammunition that is manufactured with a frangible bullet is designed to minimize the dangers from ricochet or unwanted barrier perforation by using a bullet that is constructed to break up or fragment upon impact with hard unyielding substrates. The energy of these smaller post-impact fragments or powder is so small that they cannot travel very far from the initial impact site. To perform this way, these bullets are made of various formulations of powdered metals held together by adhesives, resins, or polymer materials. In contrast to the formulations that are bonded together, at least one manufacturer has developed a line of frangible ammunition that instead incorporates a jacket to encase the frangible core. Because of this novel design, the manufacturer claims that their bullets will also behave on soft organic targets as they behave on hard unyielding materials (i.e., by breaking up into small pieces). The properties of several brands of frangible ammunition were tested in scenarios that could be encountered in a shooting scene.

Several types of frangible ammunition that included a variety of construction methods and constituents were analyzed. Cartridges from different manufacturers were disassembled and the bullets were cross-sectioned to gain an understanding of their construction. Stereomicroscopy was used to assess how the bullet was made and its constituents; then Scanning Electron Microscopy with Energy-Dispersive X-ray Spectroscopy (SEM/EDS) was used to identify the elements present. The impact dynamics of the various frangible bullets tested were compared to traditional Full Metal-Jacketed (FMJ) bullets with unyielding material (steel plate) and yielding materials (wet sponge and sheet metal). The frangible bullets were also assessed based on their ability to accept individual markings (i.e., stria) from passage down the barrel of the firearm. High-speed photography was used to gain an understanding of the bullet's performance characteristics on the aforementioned yielding and unyielding materials.

Recovered bullet or jacket fragments were examined microscopically to determine if stria were present from the barrel's rifling and, if so, whether they were useful for comparison purposes. Frangible bullets that were encased within a traditional jacket did retain stria from the barrel and were able to be compared successfully to other test-fired bullets from the same firearm. Those that were not jacketed and were made of composites of powdered metal and adhesive only had class characteristics imparted from the rifling of the firearm's barrel. While the conventional FMJ bullets remained intact after 15-degree incident-angle impact with steel plate, most frangible bullets broke up into fragments upon impact with the same steel plate. Some of these post-impact bullet fragments were still relatively large and retained enough energy to pose a danger at close range.

Frangible, Bullet, Comparison Microscopy

B166 Development of a New Standard Bullet for Ballistic Quality Control

Thomas B. Renegar, BS, NIST, 100 Bureau Drive, MS 8212, Gaithersburg, MD 20899; Xiaoyu A. Zheng, MS, NIST, 100 Bureau Drive, MS 8212, Gaithersburg, MD 20899; Robert M. Thompson, BS, NIST, Special Programs Office-Forensic Sciences, 100 Bureau Drive, MS 8102, Gaithersburg, MD 20899; Theodore V. Vorburger, PhD, NIST, 100 Bureau Drive, MS 8212, Gaithersburg, MD 20899; Junfeng J. Song, MS, NIST, 100 Bureau Drive, MS 8212, Gaithersburg, MD 20899; Johannes A. Soons, PhD, NIST, 100 Bureau Drive, MS 8223, Gaithersburg, MD 20899; and James H. Yen, PhD, NIST, Statisical Engineering Division, 100 Bureau Drive, MS 8980, Gaithersburg, MD 20878-8980*

After attending this presentation, attendees will understand the importance of the National Institute of Standards and Technology (NIST) Standard Bullet and how it relates to ballistic measurement quality control and traceability. Attendees will also understand polymer replication and metal-coating techniques.

This presentation will impact the forensic science community by demonstrating a method of ensuring quality control for ballistic measurements. This is important in how it relates to standardization organizations and laboratory accreditation.

This presentation describes the development of the next generation Standard Reference Material (SRM) Standard Bullet. The original Standard Bullet (SRM 2460) was developed by NIST to provide a standardized physical artifact for forensic laboratories to demonstrate quality control and measurement traceability.

Forensic laboratories that perform ballistic comparisons have come under scrutiny in recent years to ensure that sound scientific methods and quality control are followed in their measurements and analysis. For ballistics identifications, it is important that measurement equipment is operating properly and appropriate measurement practices are followed. The original NIST SRM Standard Bullet, developed more than ten years ago, has been an invaluable tool for forensic examiners.[1] By using the Standard Bullet, examiners ensure their measurements, comparisons, and analysis of bullet evidence are done properly. Examiners are also able to show measurement traceability, which allows measurement comparisons to be performed with other laboratories.

The original NIST SRM 2460 Standard Bullet is no longer available. A suitable replacement is needed that will meet the needs of forensic laboratories. The replacement Standard Bullet must meet several requirements: (1) it must have similar topography to that of the original Standard Bullet; (2) surface features (striations) must be consistent from one unit to the next so comparisons between laboratories can be performed; (3) it must be cost effective; and, (4) it must be durable for laboratory use. The original Standard Bullet was manufactured using a diamond turning machining process, which was time consuming and expensive. Therefore, an alternative manufacturing process was developed.

Polymer replications were produced from original master bullets using silicone molding and polymer casting techniques. Originally developed by the Bundeskriminalamt (BKA) in Germany and improved by NIST, a suitable manufacturing process was developed.[2] Several challenges that were faced will be discussed, including removal of micro-bubbles from the silicone and polyurethane mixtures. This is crucial to producing clean replications free of bubbles and other contaminations. Durability of the bullets is also important for laboratory use. Techniques used to harden the surface of the polymer replicas, including gold coating, will be presented. The manufacturing process for producing more than 100 bullets will also be discussed as well as the measurements/analysis performed to ensure the quality of all bullets produced.

Going forward, the new Standard Bullet will be a key part of ensuring bullet comparisons are performed using quality-control practices. This will be an important part of laboratory accreditation. New documentary standards that are currently being developed by the Organization of Scientific Area Committees (OSAC) will undoubtedly require laboratories to follow quality-control practices and demonstrate measurement traceability. The new Standard Bullet will help fulfill these requirements.

B167 Analyzing a Firearms Proficiency Test Using the Congruent Matching Cells (CMC) Method of Computer-Aided Topography Comparisons

Daniel Ott, PhD, NIST, 100 Bureau Drive, Mail Stop 8212, Gaithersburg, MD 20899; Robert M. Thompson, BS, NIST, Special Programs Office-Forensic Sciences, 100 Bureau Drive, MS 8102, Gaithersburg, MD 20899; and Junfeng J. Song, MS, NIST, 100 Bureau Drive, MS 8212, Gaithersburg, MD 20899*

After attending this presentation, attendees will understand how computer algorithms can be used as a powerful tool for firearms examiners to quickly identify potentially matching regions on a surface.

This presentation will impact the forensic science community by addressing concerns about the scientific method in forensic science through the use of quantitative surface comparison algorithms and drawing connections to comparisons made by human examiners.

The underlying technology in this presentation is a computer algorithm developed at the National Institute of Standards and Technology (NIST) to compare impressed tool marks on ballistics evidence in an impartial, automatic, and quantifiable way. The algorithm is called the CMC method, which is based on the discretization of a surface into cells that are compared individually with another surface. The registration location of each cell is found which corresponds to the location of highest physically similarity on the other surface. Cells registered in the same relative orientation on the second surface are considered congruent and the number of congruent matching cells constitutes a similarity score. The CMC method has been effectively used to analyze select sets of data containing known matching and known non-matching tool mark pairs.[1] One of the key advantages of this method is that it is effective in isolating valid areas that contain unique surface topography from invalid areas without unique surface topography. In a way, this is similar to the human examiner's ability to disregard an area on a surface that is damaged, has pre-fired surface features, or does not contain useful features for correlation. Therefore, a direct comparison of the regions used to justify identifications can be made. This feature also allows the CMC method to be used as a tool to help a trained examiner quickly identify potentially matching regions for further scrutiny.

In this experiment, the CMC method was applied to a firearms comparison proficiency test administered by Collaborative Testing Services (CTS). The results of this proficiency test, along with comments by test takers, are provided by CTS. Therefore, the computer comparison algorithm can be directly compared with known data and known results from human examiners. The CTS test set was also analyzed under a comparison microscope. The features that were identified using the comparison microscope will be presented along with the areas that were identified as contributing to a match using the CMC method. These results will be supplemented with results and comments published by CTS regarding this test. A summary of the various evaluations shows that certain features are more easily identified using computer algorithms, but a holistic approach which utilizes the examiner's knowledge of firearm mechanics and class, sub-class, and individual characteristics is necessary to make informed ballistic evidence comparisons.

By identifying features that examiners and computers are able to effectively detect, a better understanding of the strengths of each type of examination technique can be reached. By combining the respective strengths of human examiners and computer algorithms, it is possible to achieve more robust and efficient surface comparisons. The primary goal is to speed up work flow by providing a tool to identify key features that could potentially match and strengthen an examiner's ability to justify and quantify their conclusions. This presentation demonstrates how the CMC method is able to achieve these goals in order to address recent concerns about the scientific method in forensic science.

Ballistics Comparisons, Proficiency Tests, CMC Method

B168 Modeling Firearm Tool Mark Persistence Through Objective Surface Metrology and Analysis

Xiaoyu A. Zheng, MS, NIST, 100 Bureau Drive, MS 8212, Gaithersburg, MD 20899; Johannes A. Soons, PhD, NIST, 100 Bureau Drive, MS 8223, Gaithersburg, MD 20899; Robert M. Thompson, BS, NIST, Special Programs Office-Forensic Sciences, 100 Bureau Drive, MS 8102, Gaithersburg, MD 20899; and Wei Chu, NIST, 100 Bureau Drive, MS 8212, Gaithersburg, MD 20899*

After attending this presentation, attendees will better understand how firearm tool marks persist over many firings. Attendees will also learn the basics of 3D measurements and analysis using the cross-correlation function as well as standard surface texture parameters.

This presentation will impact the forensic science community by providing objective support for the reproducibility of firearm tool marks over many firings. This research builds upon previous research in which examiners were able to visually identify the first test fire against the rest of the persistence test fires. This presentation will also provide quantitative analysis of how the marking surface is changing over time.

The study objective is to quantify the microscopic changes to the marking surfaces of a firearm (land, breech face, and firing pin) and how these changes affect the reproducibility of the generated tool marks on bullets and cartridge cases. The 2008 Ballistics Imaging report stated, "The validity of the fundamental assumptions of uniqueness and reproducibility of firearms-related tool marks has not yet been fully demonstrated."[1] The report also state, "A designed program of experiments covering a full range of sources of variability is important to test the fundamental assumptions, as well as to better document phenomena like "settle-in" effects."[1] Previous research has been conducted to evaluate the level of persistence seen on firearm tool marks using visual comparisons of test fires throughout the lifetime of the firearm.[2,3] These studies have concluded that examiners are able to visually identify Test Fire 1 with the rest of the persistence sets. They also noticed wear over time and slight changes to the tool marks created.

The current research seeks to provide more objective measurement and analysis to quantify how the tool marks are changing over time. The degree of similarity between bullets and cartridge cases are evaluated using the maximum value of the normalized Cross Correlation Function (CCF) or Areal Cross Correlation Function (ACCF). To quantify the physical changes of the tool marks, standard surface texture parameters found in the American Society of Mechanical Engineers (ASME) B46.1-2009 are used.[4] These include arithmetic mean deviation of the assessed profile/surface (Ra, Sa), root mean square deviation of the assessed profile/surface (Rq, Sq), maximum profile peak height (Rp, Sp), maximum profile valley depth (Rv, Sv), and total height of the profile (Rt, St). The test fires used in this research were generated by the following groups: (1) Alameda County Sheriff's Office Crime Lab. Two thousand bullets and cartridge cases fired from a new Ruger® P89 pistol. The first ten, then every 25th, test fire was collected; (2) Indiana State Police Laboratory. Ten thousand bullets and cartridge cases fired from three new Beretta® 96G pistols. First three, then three more test fires at 500-round intervals were collected.

Measurements were taken with a disc-scanning confocal microscope which generates 3D topographic data. A 10X objective with 0.3NA was used for breechface measurements and a 20X objective with 0.6NA was used for firing pin and bullet measurements. Standard Gaussian filters were applied to extract the pertinent individual tool marks used for identifications. Several experiments were conducted to show the trend in CCF/ACCF and surface texture parameters over the test fire sequences. This research helps to provide more objective analysis of firearm persistence as well as evaluate the reproducibility of tool marks from a firearm.

B169 Proposed Congruent Match Cross-Section (CMX) Method for Ballistics Identification of Firing Pin Impressions

Junfeng J. Song, MS, NIST, 100 Bureau Drive, MS 8212, Gaithersburg, MD 20899; Mingsi Tong, PhD, NIST, 100 Bureau Drive, MS 8212, Gaithersburg, MD 20899; Hao M. Zhang, PhD, NIST, 100 Bureau Drive, MS 8212, Gaithersburg, MD 20899; Wei Chu, NIST, 100 Bureau Drive, MS 8212, Gaithersburg, MD 20899; and Robert M. Thompson, BS*, NIST, Special Programs Office-Forensic Sciences, 100 Bureau Drive, MS 8102, Gaithersburg, MD 20899*

After attending this presentation, attendees will understand how to use a new method called the CMX Method developed at the National Institute of Standards and Technology (NIST) for ballistics identification of firing pin impressions.

This presentation will impact the forensic science community by providing a new method — the CMX Method — for fast and accurate ballistics identification of firing pin images.

Reporting an error rate for forensic evidence identification is a fundamental challenge in forensic science.[1] It is a national priority to establish a scientific procedure for quantitative error rate reports to support firearm and impression identifications in court proceedings.[2] The Congruent Matching Cells (CMC) method was recently invented at the NIST for accurate image-related forensic evidence identification and error rate estimation.[3,4] The CMC method is based on the principle of discretization — it divides the entire image into small correlation regions and uses multiple identification parameters for accurate forensic evidence identification. This enables the estimation of error rates and the Likelihood Ratio (LR) based on statistical analysis of the total number of correlation cells, the number of qualified CMC cell pairs, and the statistical distribution of the four identification parameters.

Validation tests of the CMC method for correlation of breechface impressions have recently been completed using 40 cartridge cases fired with consecutively manufactured pistol slides.[5] These tests include 717 Known-Non-Matching (KNM) and 63 Known-Matching (KM) image correlations. The results do not produce any false positive or false negative identifications and hence provide strong initial support for the effectiveness of the CMC method for correlation of the breechface impressions. An approach for calculating error rates has also been developed using the CMC method.[4]

Firing pin impressions on cartridge cases are an important part of firearms evidence identifications; however, in comparison to the CMC correlation for breechface impressions with millimeter-sized correlation areas, there is only a limited correlation area (sub-millimeter) on the firing pin impressions. Furthermore, the concave shape of firing pin impressions makes it difficult for automatic correlations. A new method and related algorithm, CMX, are proposed for correlation of firing pin impressions. Each firing pin impression is sliced into layers; their circular cross-sections are converted into linear profiles by the polar coordinate transformation. The areal spline filter is used for extracting the high-frequency micro-features, or the individual characteristics, for accurate correlation.[6-8] Three identification parameters are proposed for determining whether these pair-wise firing pin impressions are fired from the same firearm. The Cross-Correlation Function (CCF) is used for quantifying similarity of the pair-wise profiles which represent the two correlated firing pin images. The registration phase angle θ is another important identification parameter: if the correlated cartridge pair is fired from the same firearm, there would be nearly a common phase registration angle between the set of profiles of the reference firing pin impression and those of the correlated firing pin impression. The vertical shift distance of the slice location h, combined with horizontal shift distance of the phase angle θ, are used for determining the congruency of the pair-wise correlated profiles. When these parameter values and their statistical distributions are collected for analysis, the CMX number is derived as a key parameter for a conclusive identification of exclusion.

The CMX method and the proposed identification algorithm were validated by 780 pair-wise firing pin topography images of 40 cartridge cases of three brands, which were fired from ten firearms from three different manufacturers. This includes 60 KM and 720 KNM image pairs. All of these topography image pairs are correctly identified based on the optimized parameters. There is a clear separation between the CMX distribution of the KM and KNM image pairs: for the 720 KNM image pairs, the CMXs are distributed from 0 to 14; for the 60 KM image pairs, CMXs are distributed from 20 to 49.[9] Although there is only a limited data size collected from three brands of 40 cartridges fired by ten firearms from three manufacturers in this study, it has demonstrated the possibility of using the proposed CMX method for correlations of large data sets of firing pin images fired from different firearms.

B170 Imparting a Meaningful Application of Statistics to Forensic Scientists

Stephen L. Morgan, PhD, University of South Carolina, Dept of Chemistry & Biochemistry, 631 Sumter Street, Columbia, SC 29208*

After attending this presentation, attendees will understand that statistical education is fundamental to the proper analysis of scientific data, including that generated by forensic laboratories. Understanding the meaning and appropriate application of statistics is vital if conclusions reached are to have validity. This presentation will discuss the examples of inappropriate and appropriate statistics that should be considered essential knowledge for the practicing forensic scientist.

This presentation will impact the forensic science community by discussing approaches to addressing inadequate applications and interpretations of statistics in forensic science by providing examples of appropriate usage and highlighting selected pitfalls in statistical methodology and interpretation.

The book, How to Lie with Statistics, states that "anything smacking of the medical profession" (or backed by scientific laboratories) is worthy of trust.[1] H. G. Wells once said, "Statistical thinking will one day be as necessary for efficient citizenship as the ability to read and write." The assault on inappropriate statistical thinking in forensics began in 2004 with the National Academy of Sciences (NAS) Report on bullet lead comparisons.[2] The following 2009 National Academy of Sciences (NAS) Report, Strengthening Forensic Science in the United States – A Path Forward, emphasized validation of forensic measurements and estimation of uncertainty of measurements to understand sources of bias/error in forensic science.[3] Just substitute "forensic scientists" for "efficient citizenship" in the Wells quote. The day is now — trust is no longer unconditional.

Education in applicable statistics is a first step. Accreditation Standards of the American Academy of Forensic Sciences (AAFS) Forensic Science Education Programs require "…at least one course in statistics (three semester hours)." There is no mention of statistics applicable to forensic practice, but budding forensic scientists have exposure to method validation in the suggested instrumental analysis course. What about a meaningful discussion of reporting confidence intervals instead of p-values, of differences between a p-value, a size effect, or a likelihood ratio; or of the fact that at a limit of detection defined by the concentration equivalent to a signal that is three standard deviations of the blank measurement higher than the average blank signal, the false positive detection rate is 50%. Houck was perhaps concerned with the "tyranny of numbers" when he wrote, "This expectation (to apply statistics) is fraught with pitfalls that could adversely affect the accuracy of evidentiary reports presented in court. The foundational data upon which trace evidence statistics might be based differ radically from those used in DNA statistical calculations. If statistics are to be applied to trace evidence, they must be applied in a way appropriate to the discipline, unbiased in interpretation, and accessible to the trier of fact".[4] Reinhart believes the problem is poor statistical education.[5] Ioannidis makes the case that even established medical scientists have issues with positive predictive value (i.e., research producing false positive outcomes).[6]

Lack of knowledge of appropriate statistics in various disciplines is not uncommon. Medical students are required to take a course in statistics, yet medical residents apparently average less than 50% correct on questions concerning statistical tests used in medicine.[7] Most forensic validation documents are now citing appropriate statistical methodology; however, few show worked examples of appropriate data treatment for determining uncertainties or offer interpretations of the statistical outcomes. At this time, there is a need for statistical tools that are designed and fit-for-purpose in forensic application. How does the community get from here to where it should be is the question raised in this presentation.

Statistics, Applicability, Interpretation

B171 Challenges for Implementing a New Paradigm in Fire Debris Analysis and Reporting

Mary R. Williams, MS, National Center for Forensic Science, PO Box 162367, Orlando, FL 32816-2367; and Michael E. Sigman, PhD, University of Central Florida, National Center for Forensic Science, PO Box 162367, Orlando, FL 32816*

After attending this presentation, attendees will understand the challenges of moving from categorical statements to statements of quantifiable evidentiary value in fire debris data interpretation.

This presentation will impact the forensic science community by demonstrating a methodology for assessing and presenting statements of quantifiable evidentiary value in fire debris analysis.

The American Society for Testing and Materials (ASTM) E1618-14 (Section 12) allows for reporting the presence or absence of ignitable liquid residue using a variety of terminology; however, "Note 5" stipulates that "[R]regardless of the choice of phrases used, there is no implied difference in the perceived level of confidence for a positive result."[1] The E1618-14 standard establishes subjectively determined dichotomous categorical statement(s) and explicitly rejects the concept of evidentiary value. This approach is not congruent with current trends in forensic science.

Many disciplines of forensic science have come under pressure to replace subjective methods and categorical conclusions with objective methods and/or statements that reflect statistical and quantifiable results. Popular ways to address this problem include the use of random match probabilities, likelihood ratios, and verbal equivalents to express the results in language that a lay jury can understand. Recent research in criminal justice and the social sciences have shed some light on the effectiveness of these three methods.[2,3] The approach that has been endorsed by the European Network of Forensic Institutes in their 2015 guideline on evaluative reporting involves the use of likelihood ratios in a Bayesian framework to express evidentiary value as a verbal scale which is tied to the likelihood ratio.[4] There are many challenges to implementing a likelihood ratio approach with verbal equivalents of evidentiary value in forensic fire debris analysis. This presentation will introduce the fundamental concepts of the approach and the benefits as well as the challenges that must be overcome to implement the approach. Topics addressed will include the need for specialized software, standard data sets, and accessible training.

B172 An Overview of Different Approaches to Expressing Significance in Associative Forensic Reports

Christopher R. Bommarito, MS, Forensic Science Consultants, 127 W Grand River Avenue, Williamston, MI 48895*

After attending this presentation, attendees will better understand the varying methods used to convey significance in forensic reports involving comparison of trace evidence.

This presentation will impact the forensic science community by providing an overview of the importance of expressing significance in forensic comparisons, the different methods currently employed to express significance, and the advantages and disadvantages of each method.

In February 2009, the National Academy of Sciences (NAS) Report, *Strengthening Forensic Science in the United States: A Path Forward was released*.[1] The Report expressed the need for the forensic community to "raise the standards for reporting and testifying" and identify in reports "the sources of uncertainty in the procedures and conclusions along with estimates of their scale (to indicate the level of confidence in the results)". This has increased the urgency among standard-setting organizations, such as the Scientific Working Group for Materials Analysis (SWGMAT), the European Network of Forensic Science Institutes (ENFSI), and the Organization of **Scientific Area Committees (**OSAC) to create standards by which analysts express significance in their reports.

Ideally, significance would be expressed with a frequency, as is done in DNA analysis. In most cases with manufactured materials, this is not possible due to both lack of information and the changing nature of the population of manufactured materials. Given these limitations inherent in expressing significance, several approaches have evolved to express significance. Many analysts have not changed their reporting from historical "could have originated from the same source" conclusions or have added statements to the conclusion to outline limitations of any associations made. While expressing limitations is an improvement over a simple "could have" conclusion, this approach does not offer context regarding the relative significance of the association.

There are longtime proponents of the use of an associative evidence scale to express various possible conclusions, strengths, and limitation to an association. This approach has been adopted by many forensic laboratories in the United States and abroad and has been the basis of attempts by some standard-setting organizations to form a consensus document on expressing significance in associative trace evidence. The evolution and practice of this approach will be outlined in this presentation. The associative scale has received criticism for being subjective and inherently unscientific.

A method that has gained support, primarily outside the United States is a Bayesian approach using likelihood ratios to express the significance of an association. The ENFSI has written a comprehensive standard supporting the use of likelihood ratios in trace evidence reports as well as examples on how such reporting should be utilized.[2] One concern over the use of likelihood ratios is that, while considered a valid statistical method, many of the frequency assumptions utilized are simple estimates and therefore also subjective. Labor-intensive frequency studies have been utilized in the calculation of likelihood ratios, but consensus has not been reached as to which frequencies to employ. Complicating matters is the necessity for these frequency studies to be repeated from geographical area to geographical area.[3] In addition, a recent study has shown that it is difficult for juries to understand the verbal conclusions assigned to describe likelihood ratios.[4]

In conclusion, this presentation will offer an overview of the current trends in expressing significance in associative trace evidence and demonstrate the benefits and limitations of each approach.

Associative Scale, Significance, Likelihood Ratios

B173 Challenges in Developing Objective Interpretation Methods for Firearm and Tool Mark Examination

Robert M. Thompson, BS, NIST, Special Programs Office-Forensic Sciences, 100 Bureau Drive, MS 8102, Gaithersburg, MD 20899*

After attending this presentation, attendees will appreciate some of the major challenges in developing objective interpretation models in support of the subjective conclusions in firearm and tool mark comparison examinations.

This presentation will impact the forensic science community by exposing some of the scientific, technological, and training hurdles to be overcome before 2D and 3D tool mark surface comparisons are accepted in court.

Over the past few years, the broad scientific disciplines that make up the "Forensic Sciences" have experienced an accelerated interest in developing scientifically validated and rigorous methods to objectively measure examination results to augment the examiner's subject-based conclusion or opinion. The impression pattern disciplines currently are the greatest focus of such research due to the fact that examination results are fundamentally cognitively constructed by the examiner's observation skill, training, and experience. Firearm and tool mark examination and identification is a field in which objective measurement of the similarity of tool mark surfaces would be valuable to assist the examiner in supporting or refining the ultimate conclusion in examinations. This Research and Development (R&D) effort has been greatly assisted by increased resolution of digital photomicrography, instruments that measure 3D topographical micro-surface topography, and modern computational hardware and software; however, there are important challenges and obstacles that have to be addressed before a successful presentation of evidence, analysis, and expert opinion are delivered in a courtroom. This presentation will review what are believed to be the primary future challenges.

Technological: The forensic science profession is a small market compared to other commercial interests; the tool mark profession is even smaller. The instrumentation used in the nascent 2D imaging and 3D topographical comparison systems must be engineered by companies who have an interest in ultimately selling their systems in the future. The instrument manufacturers also must be convinced of the value in employing international standards in file transfer/sharing so that interoperability is baked into their technology from the onset. Additionally, each system brings performance strengths and weaknesses so it is probable that a number of objective comparison schemes must be tested and validated.

Measurement of Error and Confidence: Objective measurement of similarity necessarily must be paired with an objective conclusion of source. The conclusion may be based on an empirically derived threshold where identification of source is supported or based on the measured similarity quantity in relation to numerous known non-match comparisons where any similarity is due to chance. Both of these approaches require statistically valid databases of fired bullets and casings where the ground truth is known. Additionally, the databases must be adequately large and represent differences in caliber, ammunition materials, and firearm production types typical to those submitted to crime laboratories. For any determination of error rate, random match, confidence, or likelihood ratio, very large databases are warranted so that any of these results are scientifically valid.

Training: The examiners must be trained with the new technology so they are comfortable with foreign concepts and protocols such as objective measurement of tool mark similarity, how that is accomplished, the mathematical/statistical underpinnings of the comparison and the results, and how the statistical weight and measurement of confidence in a comparison is reported and best testified to a lay jury. Some thought and research on how to "model" accurate communication of these principles for testimony is required. Training the legal profession and judges in these "new" methods may be lacking and only conveyed in adversarial court settings in many jurisdictions. Having a robust and vigorously validated technology and method for casework is necessary for a successful adoption of the future tool mark comparison methods.

Objective Comparison, Firearm and Tool Mark, Similarity Measurement

B174 Mixture Interpretation and Statistics Town Hall Meeting

Kristy Kadash, PhD, Jefferson County Regional Crime Lab, 200 Jefferson County Parkway, Golden, CO 80401; Todd W. Bille, MS, Bureau of ATFE, National Laboratory Center, 6000 Ammendale Road, Ammendale, MD 20705; Charles H. Brenner, PhD*, 6801 Thornhill Drive, Oakland, CA 94611-1336; Michael D. Coble, PhD*, 100 Bureau Drive, MS 8312, Gaithersburg, MD 20899-8312; Norah Rudin, PhD*, 650 Castro Street, Ste 120-404, Mountain View, CA 94041; and Joel D. Sutton, MSFS*, 4930 N 31st Street, Forest Park, GA 30297-5205; Brad Jenkins, MS*, 700 N 5th Street, Richmond, VA 23219*

After attending this presentation, attendees will have a greater understanding of the impact that biological phenomena, amplification artifacts, and making assumptions can have on the conclusions that are drawn from DNA mixture profiles.

This presentation will impact the forensic science community by providing an open forum for discussing key factors in DNA profile interpretation.

The primary objective of this session is to share opinions and experiences regarding mixture interpretation. Forensic DNA interpretation is in a period of transition or, to use the theme of the 2016 meeting, a period of "transformation." It is clear that a "cookbook" approach to analyzing mixtures is not feasible and that a static set of rules cannot be applied to the interpretation of every DNA profile; however, it may be possible to generate a list of technological and biological phenomena for analysts to consider throughout the analysis and interpretation process. Likelihood Ratios (LR) are now considered to be the more appropriate statistical method for the majority of mixture conclusions. In addition, sophisticated modeling algorithms (probabilistic genotyping) are being employed to account for the behavior of DNA during Polymerase Chain Reaction (PCR) amplification. There is a great deal of uncertainty in how to apply probabilistic genotyping and LRs, particularly concerning what assumptions to make and what factors to incorporate for allele sharing, relatedness, stochastic events, PCR artifacts, and other casework scenarios. Furthermore, how should these assumptions and conclusions be documented, reported, and presented in court?

Rather than holding individual presentations on this topic, this Special Session of the Criminalistics Forensic Biology Scientific Session is intended to be an interactive discussion. This will not be a series of demonstrations of various software programs or theoretical explanations of the mathematical formulas. Instead, six panelists from diverse backgrounds (practitioners, researchers, mathematicians, and legal consultants) will be on hand to share their perspectives on the proper thought process for arriving at scientifically valid conclusions during mixture interpretation. The session will be driven primarily by questions solicited from DNA analysts ahead of time, from selected examples of complex mixtures, and from questions generated during the Special Session. The goals at the end of the session are for the audience to feel more confident in their approach to mixture interpretation based on the advice and experience provided by the panel and to be aware of the options available for statistical modeling of PCR-based DNA data. As a result, the forensic DNA community may grow or "transform" to keep in step with the complex types of mixtures that are becoming more prevalent in routine casework.

Mixture Interpretation, Probabilistic Genotyping, Statistics

B175 Optimization and Validation of Mitochondrial DNA (mtDNA) D-Loop Sequencing on the MiSeq®

Laura A. Wilson, BS, Penn State University, 107 Whitmore Lab, University Park, PA 16802; Sarah Copeland, BS, 300 Farmstead Lane, #8, State College, PA 16803; Gloria Dimick, MS, 2565 Park Center Boulevard, Ste 200, State College, PA 16801; Charity A. Holland, MPH, Mitotyping Technologies, 2565 Park Center Boulevard, Ste 200, State College, PA 16801; Robert Bever, Mitotyping Technologies, 2565 Park Center Boulevard, Ste 200, State College, PA 16801; and Mitchell M. Holland, PhD, Penn State University, 107 Whitmore Laboratory, University Park, PA 16802*

After attending this presentation, attendees will better understand how transcriptase-adapted Polymerase Chain Reaction (PCR) primers compare to the conventional PCR primers used today by forensic laboratories in the sequencing of the mitochondrial D-loop and the impact this comparison will have on the forensic science community.

This presentation will impact the forensic science community by aiding forensic laboratories in the adoption of a next generation sequencing approach when using the human mitochondrial D-loop protocol from the Illumina® MiSeq® instrument. Through heteroplasmy detection and reporting, sequencing the D-loop with a next generation approach on the MiSeq® will also increase the discrimination power of the testing method.

The mtDNA is present in high copy numbers, making it a powerful tool for analyzing forensic samples such as hair shafts and aged skeletal remains.[1,2] The non-coding region, or D-loop, is the target most often analyzed by forensic laboratories and contains two hypervariable regions known as HVR1 and HVR2; 16,024-16,365 and 73-340, respectively.[3] Sequencing the D-loop with a next generation approach on the MiSeq® will increase the discrimination power of the testing method via heteroplasmy detection and reporting. The D-loop protocol from Illumina® utilizes two sets of conventional, overlapping PCR primer pairs that span the hypervariable regions, with each primer possessing a transposase sequence added to the 5'-end that allows for library preparation prior to analysis on the MiSeq®.[4]

The first-round PCR amplification with Transposase Adapted (TA) primers was optimized and compared to the conventional primer pairs used today by forensic laboratories. The main difference between the two protocols (besides the modified primers) is the use of AmpliTaq® Gold® DNA polymerase versus Ex Taq™ Hot Start from TaKaRa, a polymerase with 3' to 5' exonuclease proofreading activity that utilizes an optimized Ex Taq™ buffer system.[5] The limitations of the PCR reaction parameters were also tested; for example, primer concentrations, magnesium concentration, and the amount of Ex Taq™ employed. The optimized amplification was used in validation studies performed by this group on the Illumina® D-loop protocol following the Scientific Working Group on DNA Analysis Methods (SWGDAM) guidelines. The studies included: (1) the evaluation of the robustness of the first-round PCR amplification when using the TA primers or the conventional primer pairs; (2) the sensitivity of library preparation by adding a range of DNA (amplicon) inputs; (3) mixture studies with various ratios of contributor DNA; (4) the evaluation of precision and accuracy through repeatability (same operator and detection instrument); and, (5) concordance experiments. These findings represent an important step toward the adoption of a next generation sequencing approach by forensic laboratories by using the D-loop protocol from Illumina® on the MiSeq® instrument.

Next Generation Sequencing, Mitochondrial D-Loop, PCR

B176 Massively Parallel Sequencing (MPS) of Microhaplotypes for Forensics

Sharon C. Wootton, PhD, 180 Oyster Point Boulevard, South San Francisco, CA 94080; Kenneth Kidd, PhD, Yale University School of Medicine, Dept of Genetics, 333 Cedar Street, New Haven, CT 06520; William C. Speed, PhD, Yale University, 333 Cedar Street, New Haven, CT 06520; Joseph P. Chang, BS, Thermo Fisher Scientific, 180 Oyster Point Boulevard, South San Francisco, CA 94080; Sheri J. Olson, MS, Thermo Fisher Scientific, 409 Roosevelt Boulevard, Half Moon Bay, CA 94019; Reina Langit, MS, 850 Lincoln Centre Drive, Foster City, CA 94404; Chien-Wei Chang, PhD, Thermofisher Scientific, 180 Oyster Point Boulevard, South San Francisco, CA 94080; and Robert Lagace, BS, 850 Lincoln Centre Drive, Mail Stop #404-1, Foster City, CA 94404*

After attending this presentation, attendees will better understand the fundamentals of MPS and its application to forensics, particularly the use of microhaplotypes for determining biogeographic ancestry and for resolving mixture and kinship scenarios.

This presentation will impact the forensic science community by demonstrating microhaplotype multi-allelic genomic markers as a forensic solution to be used in conjunction with other Single Nucleotide Polymorphism (SNP) and Short Tandem Repeat (STR) markers in an MPS context. This presentation will show analysis from experiments designed to test the sensitivity of mixture detection, to define the ancestry prediction resolution, and to measure the accuracy of kinship analysis.

Recent studies demonstrating the use of MPS in forensics have shown a new methodology for interrogating a wide range of genomic markers beyond STRs, including mitochondrial DNA(mtDNA), messenger RNA (mRNA), and SNPs for identity, biogeographic ancestry, and phenotype.[1,2] The flexibility of a small amplicon, highly multiplexed, genomic assay enables the analysis of degraded or low template DNA samples. The additional resolution of sequence differences plus fragment length for an STR locus supplements the analysis of familial relationships and the deconvolution of mixtures.

When multiple SNPs reside within a single sequencing read (~<300bp), there may be multiple haplotypes represented as statistically phased SNP genotypes.[3] These multiallelic markers, like STRs, provide an excellent tool for kinship and mixture analysis. Additionally, some microhaplotypes may be used to derive biogeographic ancestry when there is large enough allele frequency variation between global populations.[3]

Forty-five microhaplotypes with high heterozygosity were selected using a set of criteria defined by Dr. Kenneth Kidd.[3] All of these have been run on a set of 54 populations by the Kidd laboratory. Primers were designed to amplify all markers in multiplex. DNA was extracted from a number of sample sources taken from individuals of different biogeographic ancestries. Mixtures were created at ratios of 1:1, 1:3, 1:7, 1:15, and 1:30. Samples were also selected to represent a number of kinship scenarios. Libraries for MPS were created by ligating barcoded sequencing adaptors. The barcoded libraries were sequenced on the Ion Torrent™ PGM™. Sequencing reads were aligned to target regions of the reference human genome; haplotypes were determined; and tertiary analysis was performed to type biogeographic ancestry, mixture ratios, minor and major contributors, and familial relationships. The multiplex was able to amplify and sequence all intended targets with <10% off-target amplicons. There was no ambiguity-calling haplotypes, and further analysis showed promise for resolving mixture components, ancestry, and kinship.

With the capacity to sequence many markers in parallel, MPS underscores the power of microhaplotypes as a forensic marker. Its use in multiplex with STRs and lineage, phenotype, and ancestry-informative SNPs could be investigated for a comprehensive forensic solution.

B177 Optimization of a Next Generation Sequencing (NGS) Protocol for Processing High-Quality Mitochondrial DNA (mtDNA) Samples

Joseph D. Ring, MS, 115 Purple Heart Drive, Dover AFB, DE 19902; Michelle A. Peck, MFS*, Armed Forces DNA Identification Laboratory, 115 Purple Heart Drive, Dover AFB, DE 19902; Erin M. Gorden, MFS*, Armed Forces DNA Identification Lab, 115 Purple Heart Drive, Dover AFB, DE 19902; Charla Marshall, PhD, Armed Forces DNA Identification Laboratory, 115 Purple Heart Drive, Dover AFB, DE 19902; and Kimberly S. Andreaggi, MFS*, ARP/AFDIL, 115 Purple Heart Drive, Dover AFB, DE 19902*

After attending this presentation, attendees will better understand the differences that exist in sequencing mtDNA using two different library preparation kits that involve enzymatic fragmentation. Additionally, attendees will learn about an optimized mtDNA library preparation protocol for sequencing on the Illumina® MiSeq®.

This presentation will impact the forensic science community by introducing an effective method for library preparation and sequencing of high-quality mtDNA samples. The kit comparisons and optimizations made will help other forensic DNA laboratories with their transition to NGS processing.

The role of the Armed Forces Medical Examiner's/Armed Forces DNA Identification Laboratory (AFMES/AFDIL) is to aid in the identification of United States service members from current and past conflicts. Past accounting DNA testing support requires a substantial amount of mtDNA reference data production. NGS improves on the current Sanger-type sequencing methodology by allowing for higher throughput and automated analysis workflows. This high-throughput capability is especially useful for reference and population sample processing, which can be time consuming with current techniques. Two kits (Illumina's® Nextera® XT and KAPA HyperPlus by KAPA Biosystems) were evaluated that can be utilized for sample library preparation for sequencing on an Illumina® MiSeq®. Protocols for these kits were optimized for both the mtDNA Control Region (CR) and the entire mitochondrial Genome (mtGenome).

The CR and mtGenome of positive control DNA and buccal swab extracts were amplified, and varying amounts of enriched product were used for the library preparation to test the range of inputs typically observed in processing. In addition to using the manufacturer's recommended full-volume reactions, kit volume reagents were reduced by half. Other conditions tested include whether clean-up steps were needed before library preparation and the optimal fragmentation conditions to produce an ideal fragment-size distribution. Sample libraries were sequenced on a MiSeq® instrument. The sample libraries prepared at full reagent volume produced similar fragment concentrations as those prepared using half-volume reagent volumes. The degree to which the sample library fragmented was found to be a useful indicator of sequencing success. Sample libraries that were fully fragmented had, on average, approximately a 200% increase in the number of sequence reads compared to those libraries that had partial to no fragmentation.

In conclusion, a viable method has been optimized for preparing and sequencing both the CR and mtGenome of high-quality reference-type samples on the MiSeq®. Reagent volumes are able to be reduced with no loss of data quality and the process is easily amenable to automation. These optimizations lower cost and increase the efficiency of the process. Sequencing the mtGenome is prohibitive with Sanger-type sequencing because it is expensive and labor intensive. NGS and the additional optimizations to the library preparation allow mtGenome sequencing to be just as practical as CR sequencing. These procedures improve upon current methodology and will help bolster identification efforts at the AFDIL.

Next Generation Sequencing, Mitochondrial DNA, Library Preparation

B178 Assessing the Impact of DNA Damage on the Interpretation of Low-Level Mitochondrial DNA (mtDNA) Heteroplasmy

Molly M. Rathbun, BS, Penn State University, 107 Whitmore Lab, University Park, PA 16802; Jennifer A. McElhoe, DPhil, Pennsylvania State University, 107 Whitmore Lab, University Park, PA 16802; and Mitchell M. Holland, PhD, Penn State University, 107 Whitmore Laboratory, University Park, PA 16802*

After attending this presentation, attendees will understand the importance of considering DNA damage effects on Next Generation Sequencing (NGS) sequence data. Attendees will also be more aware of how these effects will be important when developing reliable guidelines for interpreting and reporting mtDNA heteroplasmy or other types of low-level Single Nucleotide Polymorphisms (SNPs) in future forensic casework. This presentation will include a discussion on extract storage conditions, characteristics and identification of false low-level variant positions, and interpretation threshold recommendations.

This presentation will impact the forensic science community by elucidating characteristics of DNA damage in the mtDNA control region as it relates to the interpretation of heteroplasmy when using the NGS technology from Illumina®, the MiSeq®. With the introduction of NGS to forensic laboratories in the near future, the effect of DNA damage on any NGS sequence data should be characterized in order to prevent reporting of false positive sequence data. Given that low-level variants have the potential to make mtDNA more discriminating by offering the ability to better distinguish between unrelated individuals and maternal family members and by offering a more statistically significant likelihood ratio, it becomes inherently important to understand how damage affects these interpretations when made in modern forensic investigations and identifications. In addition, this information will contribute to understanding how damage may impact the analysis of nuclear DNA SNPs. There is confidence that this study of the impact of DNA damage on mtDNA heteroplasmy observations will help lead to recommendations of best practices for NGS forensic applications.

Forensic mtDNA analysis is a robust technique that is advantageous for challenging samples, but the identification through maternal haplotypes limits the discrimination potential compared to Short Tandem Repeat (STR) analysis. Heteroplasmic sequence variants can potentially provide distinction between maternal relatives and significantly increase likelihood ratios associated with matching mtDNA profiles; however, the nature of heteroplasmy as mixtures means that other sources of mixtures, such as DNA damage, must be eliminated as the cause of an apparent variant.[1] DNA damage is frequently encountered in forensic mtDNA analysis, so it is important to understand its effect on the interpretation of heteroplasmy. NGS of DNA now offers higher sensitivity than the Sanger method, allowing for detection of low-level heteroplasmy with a 1% minor variant.[2,3] Given that damaged sites can be observed with the Sanger method of sequencing, it was anticipated that damage will impact heteroplasmy interpretation using an NGS approach. Considering that mtDNA heteroplasmy may someday be more widely reported in forensic casework, a clear understanding of how damage-related anomalies affect NGS data will be important to the forensic community.

The goal of this study was to characterize the impact of DNA damage on the interpretation of mtDNA heteroplasmy, mainly in regard to low-level variants. The conditions that encourage damage mechanisms, such as deamination, which may arise from storage of DNA extracts or postmortem exposure to the element, were modeled.[4,5] Samples were run on the Illumina® MiSeq® following Nextera® XT library preparation. The sequencing data showed concordance with the Sanger method, providing consistent haplotypes across all conditions and maintaining the reliability of common DNA extract storage practices; however, it was discovered that when using an interpretation threshold of 1% for low-level heteroplasmy, as damage conditions become more intense, the number of apparent heteroplasmic positions increased. A decrease in the expected transition/transversion ratio was observed, suggesting that the sites of damage were random in relation to normal mutation mechanisms. Also, most of the false heteroplasmic positions showed a 1%-2% minor variant, with certain positions more likely to show false heteroplasmy. This may be useful for separating out and reporting true variants as interpretation criteria are developed.

Altogether, the results of this study of DNA damage advocate for careful consideration of long-term extract storage methods. NGS data produced from challenging evidence samples such as these will impact threshold considerations for reporting low-level heteroplasmy in future mtDNA casework. This assessment will also help contribute to the recommendations of best practices for forensic NGS-reporting guidelines as this technology is incorporated into crime laboratories.

MiSeq®, MtDNA Heteroplasmy, DNA Damage

B179 Comparison of DNA Repair Methods for Improved Success With Next Generation Sequencing (NGS) of Compromised Skeletal Remains

Erin M. Gorden, MFS, Armed Forces DNA Identification Lab, 115 Purple Heart Drive, Dover AFB, DE 19902; Charla Marshall, PhD*, Armed Forces DNA Identification Laboratory, 115 Purple Heart Drive, Dover AFB, DE 19902; and Kimberly S. Andreaggi, MFS*, ARP/AFDIL, 115 Purple Heart Drive, Dover AFB, DE 19902*

After attending this presentation, attendees will be aware of the existence of DNA damage in common forensic samples in both Sanger sequencing and NGS data. This presentation will address ways to overcome this damage using DNA repair kits.

This presentation will impact the forensic science community by demonstrating how DNA damage from common forensic samples (such as bones and teeth) can impact analysis of both Sanger and, to a larger degree, NGS results. This presentation will also exhibit the ability of various kits to repair the damage.

The Armed Forces DNA Identification Laboratory (AFDIL) was established with the primary purpose of employing DNA techniques to assist in the identification of remains of United States service members. The identification of compromised skeletal remains by the AFDIL's past accounting section is achieved by using a combination of analysis types: mitochondrial DNA (mtDNA), autosomal Short Tandem Repeat (STR), and Y-chromosomal Short Tandem Repeat (Y-STR) testing; however, the condition of skeletal remains, including exposure to environmental insults and chemical treatment, can present a challenge in obtaining results due to DNA degradation and Polymerase Chain Reaction (PCR) inhibition. NGS can aid in the identification process by yielding results for such damaged and degraded samples in a more cost-effective and high-throughput manner than current methodologies. For these reasons, NGS methods are currently being optimized and validated for degraded DNA casework at the AFDIL.

Several skeletal elements that spanned a quality range typically encountered in past accounting cases as well as appropriate controls were enriched for the mtDNA control region using mini-primer sets (125bp-180bp). Following PCR enrichment, library preparation was performed for sequencing on the Illumina® MiSeq®. The NGS data for the positive controls were of good quality and generated the expected profiles; however, erroneous variants were detected at nearly every position across the targeted regions for the low-quality casework samples. These errors were observed at variant frequencies as high as 30% and consisted mostly of GàA and CàT mutations, which is indicative of DNA damage due to cytosine deamination. Sanger sequence data confirmed the presence of DNA damage, but at a level that did not impact variant calling due to the qualitative nature of this type of analysis. Furthermore, a decrease in Guanine-Cytosine (GC) content was observed in the sequences from the skeletal samples, providing additional evidence of DNA damage.

To address the DNA damage in casework samples, two methods of DNA repair were evaluated: the NEBNext® Formalin-Fixed Paraffin-Embedded (FFPE) DNA Repair Mix and Uracil-Specific Excision Reagent (USER™) Enzyme. In an initial study, improved sequence results were obtained from six casework samples that underwent repair treatment in comparison to the untreated extracts. Approximately 20% of sequences in repaired samples showed a shift in GC, indicating damage, compared to 70% in untreated samples. The number of mapped reads generated with NEBNext® FFPE repair-treated samples was closest to that of the untreated samples (two to three times higher than those treated with the USER™ enzyme), resulting in greater coverage across the targeted regions. The low number of reads obtained with the USER™ protocol is most likely the result of a required clean-up step in which DNA loss is expected. This step is not necessary in the FFPE protocol, making it a more attractive option for use with low-quantity samples. In most cases, unauthentic low-level variants observed in the untreated samples were eliminated in the repaired extracts. The results of this work suggest that DNA repair of compromised samples will not only be necessary for NGS processing but will also be beneficial for current Sanger sequencing of skeletal remains performed at the AFDIL. As the forensic community continues to look toward NGS for its increased sensitivity and low-level variant detection capability, DNA damage in low-quality specimens must first be addressed in order to generate reliable data.

Next Generation Sequencing, DNA Damage, DNA Repair

B180 Sequence-Based Analysis of Stutter at Short Tandem Repeat (STR) Loci: Implementation and Utilization

Rachel Aponte, 9815 Bristol Square Lane, Apt 301, Bethesda, MD 20814; Katherine B. Gettings, PhD, NIST, 100 Bureau Drive, MS 8314, Gaithersburg, MD 20899; David L. Duewer, PhD, 100 Bureau Drive, Gaithersburg, MD 20899; Becky Hill, MS, 100 Bureau Drive, MS 8311, Gaithersburg, MD 20899; Michael D. Coble, PhD, 100 Bureau Drive, MS 8312, Gaithersburg, MD 20899-8312; and Peter M. Vallone, PhD, 100 Bureau Drive, Gaithersburg, MD 20899-8311*

After attending this presentation, attendees will understand the properties of Polymerase Chain Reaction (PCR) stutter artifacts observed in data obtained using Next Generation Sequencing (NGS) technologies and Capillary Electrophoresis (CE) methods.

This presentation will impact the forensic science community by laying a foundation for artifact interpretation guidelines, which will be required prior to implementation of NGS technologies. Observing how stutter artifacts characterized by NGS systems compare to those in traditional CE systems will help establish these guidelines. The characterization of stutter with NGS will aid in single-source data interpretation, mixture interpretation, and allow for sequence-based stutter thresholds to be set.

NGS technologies provide the potential for deeper analysis of forensic DNA samples compared to the currently employed length-based CE methods because NGS yields the full DNA sequence of each allele opposed to only the number of repeat units obtained by CE. Access to the full sequence can further individualize a DNA fingerprint by allowing specific base changes or changes within the repeat patterns of more complex loci to be observed. This is particularly useful when multiple alleles at a locus overlap with length-based genotyping but can be distinguished with NGS based on differences within the sequence motif.

NGS systems hold promise for advances in forensic DNA typing, but they will require a new understanding of artifacts and the corresponding interpretation guidelines in order to be beneficial for the forensic community. Stutter artifacts may behave differently with NGS data than what has been observed in CE data due to the differences in the system workflows. Characterization of stutter events between NGS and CE was obtained using the Promega® AutoSeq™ and PowerPlex® Fusion STR multiplex amplification kits, respectively. This study will be expanded to evaluate if stutter events are consistently observed across assays between the instrument platforms.

For the common tetra-nucleotide STR loci, stutter is commonly seen at the n-4 position in both CE and NGS data, but may be observed more frequently at the n+4 and n-8 positions in NGS data. It is possible that the higher frequency of stutter is due to a higher sensitivity of the instrumentation, but it is also possible that these go undetected due to the thresholds set for CE instruments. Lowering the threshold for CE data down to ten Relative Fluorescent Units (RFUs) allows for a better comparison with stutter from NGS systems, which currently have no established thresholds. Comparing stutter between the two systems will provide insight into how the differences of NGS workflows may affect artifacts, and thus, data interpretation. Analyzing each locus and the various types of stutter associated with each allele by sequence will allow for the establishment of allele- and sequence-specific stutter thresholds, which may further benefit current models used for mixture interpretation.

Access to the sequence of each allele also allows for general characterization of where stutter occurs within the repeat motif and whether it is primarily related to the Longest Uninterrupted Stretch (LUS) or to the total number of repeats within an allele.[1] Compound and complex loci — including D2S1338, D3S1358, D8S1179, D19S433, D21S11, FGA, and vWA — have an abundance of alleles with different motifs and would therefore benefit from sequence-based stutter thresholds. Observing the LUS of an allele opposed to observing alleles solely based on the total repeat number may provide a more accurate representation of stutter artifacts for each sequence. For example, results from data analysis of a 14 allele at locus D8S1179 demonstrates differences in stutter ratios when comparing simple and compound repeat motifs. The compound 14 allele with a LUS of 12 exhibited less stutter than the simple motif 14 allele. Therefore, targeting the LUS will allow for even more accurate stutter thresholds to be implemented.

Next Generation Sequencing, Stutter Artifacts, STR Loci

B181 Light It Up: Fluorescent Biosensors for the Detection of Biological Fluids and Fingerprints

James Gooch, King's College London, 150 Stamford Street, Waterloo, London SE19NH, UNITED KINGDOM; Barbara Daniel, PhD, King's College London, 150 Stamford Street, Waterloo, London SE19NH, UNITED KINGDOM; Vincenzo Abbate, PhD, King's College London, 150 Stamford Street, Waterloo, London SE19NH, UNITED KINGDOM; and Nunzianda Frascione, PhD, King's College London, 150 Stamford Street, Waterloo, London SE19NH, UNITED KINGDOM*

After attending this presentation, attendees will better understand biosensing technology and its potential for application toward the simultaneous detection and identification of biological fluids as a replacement for traditional serological testing. Attendees will also be aware of how this approach can be extended to other forensically relevant targets, including fingerprints.

This presentation will impact the forensic science community by introducing new techniques that are able to offer the rapid, non-destructive, and highly specific multiplex analysis of biological fluids at crime scenes. It is hoped that this presentation will also encourage researchers to utilize biosensor technology for the detection of other forensic analytes in their relative fields of expertise.

The search for body fluids often forms a crucial element of many forensic investigations. Confirming fluid presence at a scene can not only support or refute the circumstantial claims of a victim, suspect, or witness, but may additionally provide a valuable source of DNA for further identification purposes; however, current biological fluid testing techniques are impaired by a number of well-characterized limitations: (1) they often give false positives (between fluids and other non-fluid substances); (2) they cannot be used simultaneously; (3) they are sample destructive; and, (4) they lack the ability to visually locate fluid depositions.[1] These disadvantages can negatively affect the outcome of a case through missed or misinterpreted evidence.[2,3]

Recent improvements in fluid assay specificity have utilized immunological testing strips for the detection of fluid-endogenous protein biomarkers; however, these testing processes do not allow for the retention of fluids following application, potentially sacrificing the opportunity for genetic profiling.[4,5] The direct detection of these proteomic markers without the removal and possible destruction of fluids may be achieved through "biosensing," in which biological interactions are transduced into observable signal outputs within the same molecular unit. High specificities make both antibody- and enzymatic-sensing elements ideal candidates for fluid analysis, while changes in fluorescence intensity upon target interaction may allow the visualization of *in situ* fluid depositions. Furthermore, the simultaneous detection of multiple fluid analytes may potentially be achieved by exploiting fluorophores of differing wavelengths in a single multiplex assay.

This study utilized two biosensing mechanisms toward the detection of biological evidence. Two fluorogenic peptide substratesreagents specific to Prostate Specific Antigen (PSA) and Kalikrein 8 (KLK8) were first utilized for the detection of human semen and sweat, respectively. Both substrates were able to successfully detect targets across a range of surfaces typical to forensic investigation with additional visualization via a direct spraying application. Substrates exhibited ideal increases in fluorescence intensity upon target interaction, even at 1:1,000 fluid dilutions, providing an opportunity for their use in contaminated deposits or those washed in removal attempts. Furthermore, promising results were displayed in the design and development of a customized displacement immunosensor specific to human semen, which was able to identify nM amounts of PSA within solution. Importantly, both sensing mechanisms explored were found to have no effect on DNA profiling processes after application to biological fluids, allowing the source of depositions to be identified without potential destruction of genetic material.

Displaying immediate and specific response to analyte presence, biosensors have the potential to prevent month-long visual evidence searches by localizing fluid depositions within a matter of seconds. Successful sensor employment is likely to lead to a significant reduction in the labor expense associated with current manual stain search and identification strategies.

Body Fluids, Biosensors, Fingerprints

B182 Streamlining Sperm Cell Detection Via Proximity Ligation Real-Time Polymerase Chain Reaction (PLiRT-PCR) With Forensic DNA Analysis

Sarah Riman, PhD, 1009 New Hampshire Avenue, NW, Apt 1, Washington, DC 20037; and Daniele S. Podini, PhD*, Department of Forensic Science, 2100 Foxhall Road, NW, Washington, DC 20007*

After attending this presentation, attendees will gain valuable insight into the research efforts carried out to develop a PLiRT-PCR assay for the confirmatory detection of spermatozoa from sexual assault evidence without the use of a microscope.

This presentation will impact the forensic science community by demonstrating that PLiRT-PCR is a methodology compatible with current DNA Short Tandem Repeat (STR) analysis and is able to detect sperm-specific proteins by using only 2µL of a forensic sample.

Sperm identification plays a critical role in forensic investigation for understanding the circumstances surrounding a crime and determining whether or not a sexual act occurred, yet current methods for sperm detection vary widely in speed, sensitivity, and specificity and can sometimes lack the ability to confirm that the test results are conclusive.

Presently, laboratories routinely use an alternate light source as an enhancement tool followed by presumptive testing of semen using the Seminal Acid Phosphatase assay. The next step can be to test for Prostate Specific Antigen (PSA/p30) with commercial immunochromatography strips; however, the only undisputable confirmatory test for the presence of semen is the microscopic observation of spermatozoa. This process can be extremely time consuming and labor intensive, and failure to identify sperm cells by microscopic examination is not conclusive for their absence.

A potential solution to this issue is PLiRT-PCR, which is designed to detect and quantitate the expression of protein markers through an antibody-protein binding reaction followed by PCR. In fact, the assay combines the specificity of an immunological reaction with the sensitivity of quantitative PCR (qPCR). Sperm-specific protein SP10 (ACRV1) has been selected for this purpose. This target is only expressed in the male reproductive tract, specific to sperm cells, and localized inside the acrosome of the spermatozoa. This location protects SP10 from environmental damage until lysis, and thus allows for successful detection with aged forensic samples.

Probes are generated by conjugating polyclonal affinity purified SP10 antibodies to DNA oligos ending either in 3' or in 5'. When probes bind to their sperm target, the DNA strands attached to the antibodies come into close proximity and bind to a complementary connecting oligo added to the solution. These oligos are then ligated, forming a new amplifiable DNA strand that can then be detected by TaqMan® real-time PCR. The quantity of the amplified DNA corresponds to the amount of SP10, which is proportional to the amount of sperm cells in the sample. Results are determined based on a Cycle Threshold (C_T) value derived from three times the standard deviation from the "No Protein Control" (NPCs) C_T average.

This presentation discusses the identification, specificity, and the limit of detection of SP10 in: (1) liquid semen; (2) semen elution from cotton swabs; (3) pure body fluids; and, (4) mixed body fluid samples in a 96-well format. Most importantly, these experiments illustrate how PLiRT-PCR can be used to streamline the workflow of sperm confirmation with the generation of a DNA profile of the perpetrator(s) involved in the sexual assault. The assay utilizes a small fraction of the total reaction. Thus, the remaining can then be used for downstream DNA extraction, quantitation, and STR amplification.

In conclusion, this method is robust, quantitative, and more sensitive than the currently used protein-based detection techniques; samples can be processed in parallel on a 96-well plate for high-throughput analysis with minimal sample consumption. In addition, it can overcome the drawbacks associated with the microscopic observation of spermatozoa and can easily be integrated into forensic laboratories as it only requires a thermocycler and a real-time PCR system.

Spermatozoa, Sexual Assault, Proximity Ligation

B183 Developmental Validation of MicroRNAs (miRNAs) for Body Fluid Identification

Carolyn Lewis, BS, Virginia Commonwealth University, 1015 Floyd Avenue, Rm 2004, Box 843079, Richmond, VA 23284; Jamie Gentry, BS, Virginia Commonwealth University, 1015 Floyd Avenue, Richmond, VA 23284; Chelsea F. Calloway, BS, 1005 Grove Avenue, #102, Richmond, VA 23220; Nerissa Peace, BS, 3270 John Robinson Lane, #12, Dumfries, VA 22026; Ariana Albornoz, MS, 3660 E Bay Drive, Apt 1316, Largo, FL 33771; Samantha R. Fleming, MS, 10306 Gunston Road, Lorton, VA 22079; Christina Hayes Nash, MS, 17901 Milroy Drive, Dumfries, VA 22026; Zendra E. Zehner, PhD, VCU School Med/Massey Cancer Center, Dept of Biochemi & Molecular Biology, 1101 E Marshall Street, PO Box 980037, Richmond, VA 23298-0037; and Sarah J. Seashols Williams, PhD, Virginia Commonwealth University, Dept of Forensic Science, PO Box 843079, Richmond, VA 23284-3079*

After attending this presentation, attendees will understand how miRNAs function and why they can be of significant value for body fluid identification in forensic casework. Attendees will be apprised of the markers that can distinguish different body fluids and understand why miRNAs may be a better molecular-based method for the identification of body fluids rather than the use of current serological tests, which are based on enzymatic activity and are often prone to false positives. Although molecular-based methods of identification have previously been introduced into the forensic science community, the research to discover body fluid-specific miRNAs was based on other methods and the data was often conflicting. Attendees will understand the concept of miRNAs as molecular markers for body fluids and be encouraged to promote the necessary research for implementation of miRNAs in forensic casework.

This presentation will impact the forensic science community by illustrating how forensic research on miRNAs continues to build evidence for their utility as forensic molecular markers.

MicroRNAs are small non-coding RNAs that are 18 to 22 nucleotides in length and have previously been identified as potential markers for the identification of forensically relevant body fluids. There is an increased interest in the use of miRNAs because their short length, cellular function, and resistance to degradation allow for easy detection in highly degraded samples, as is often the case in forensic casework samples.

High-Throughput Sequencing (HTS) of three to four donations each of feces, urine, peripheral blood, menstrual blood, vaginal fluid, semen, saliva, and sweat was performed. The data analysis identified several candidate miRNAs with potential body fluid specificity. Initial Real-Time quantitative Polymerase Chain Reaction (RT-qPCR) evaluations revealed that while no evaluated miRNA was absolutely body fluid specific, miRNAs were identified in most body fluids with significantly different relative expression levels, which allows for body fluid identification using a panel of miRNAs. Each of the candidate miRNAs was evaluated thoroughly using classic developmental validation methods including species specificity, limit of detection, abundance within the population, and abundance within an individual over a certain period of time. The miRNAs let-7g and let-7i were identified and validated as candidate miRNAs for internal control purposes as they were expressed with consistent levels in each body fluid from all tested donors. A standard curve using a synthetic miRNA of known quantity was developed to gain a more accurate quantitation method. Based on these data, miRNAs, or the combination of certain miRNAs, can be valuable forensic molecular markers for body fluid identification, especially in degraded or low copy-number samples.

MicroRNA, Body Fluid Identification, Validation

B184 Recent Progress in the Development of a Surface-Enhanced Raman Spectroscopy (SERS) Platform for Rapid Identification of Trace Amounts of Human Body Fluids

Jennifer Fore, PhD, Boston University, Photonics Center-Dept of Chemistry, 8 St. Mary's Street, Boston, MA 02118; Ranjith Premasiri, PhD, Boston University, Dept of Chemistry, 590 Commonwealth Avenue, Boston, MA 02215; Kathryn A. Zegarelli, BS, 55 Deerfield Street, #2, Boston, MA 02215; Brandon Scott, PhD, Boston University, 8 St. Mary's Street, Boston, MA 02215; Jessica Irvine, BS, Boston University School of Medicine, 72 E Concord Street, Boston, MA 02118; Amy N. Brodeur, MFS, Boston University School of Medicine, Biomedical Forensic Sciences, 72 E Concord Street, R806, Boston, MA 02118; and Lawrence Ziegler, PhD, Boston University, Dept of Chemistry, 590 Commonwealth Avenue, Boston, MA 02215*

After attending this presentation, attendees will gain an appreciation for the developing advances in a SERS-based platform that may result in a new capability for forensics investigators at crime scenes to detect and identify trace amounts of human body fluids with a rapid, easy-to-use single instrument.

This presentation will impact the forensic science community by providing quantitative results of the use of a SERS-based methodology for the identification of dried blood, semen, saliva, vaginal fluid, menstrual blood, and urine from a single portable platform. No such capabilities currently exist in the forensic science community.

The identification of trace amounts of human body fluids, such as blood, semen, vaginal fluid, saliva, and urine, is often central to understanding events at a crime scene. Currently, a variety of tests for detection and confirmatory identification for each of the body fluid types may be carried out. For example, Kastle-Meyer, Takayama, or antibody immunochromatographic strip tests for blood, Prostate Specific Antigen (PSA) detection for semen, Lugol's iodine reaction or messenger RNA (mRNA) -based hormone detection for vaginal fluid, and alpha amylase detection of saliva; however, these individual tests have limitations in terms of sensitivity, specificity, and on-site portability in addition to speed. A portable SERS-based methodology offers the possibility of a single-platform instrument for confirmatory identification at crime scenes with higher sensitivity and specificity and is faster than techniques currently commercially available to crime scene forensic investigators. Progress in the development of a portable, universal body fluid-detection platform is described here.

SERS spectra of dried blood, semen, vaginal fluid, saliva, and urine from multiple donors (360 spectra) were collected by a simple sample protocol which uses 1nL-100nL of body fluid and exhibits reproducible SERS spectra on Au nanostructured substrates.[1] A Partial Least Squares Discriminant Analysis (PLSDA) -based classification procedure results in 98.0% sensitivity and 99.5% specificity. The novel aspect of this classification procedure that permits this robust performance is that the inputs to the PLSDA are barcode representations based on the second derivative of the SERS spectra.[2] In a further test of methodology, 60 SERS spectra of semen from multiple donors that were not used to build the model were used to challenge this identification procedure. The PLSDA correctly identifies 58/60 SERS spectra, and the resulting set of 360 spectra shows (cross-validation) 96.7% sensitivity and 99.2% specificity.

When menstrual blood is added to this developing SERS library, it is identified as a separate body fluid and the resulting six body fluid PLSDA-classification model results in 96.1% sensitivity and 99.2% specificity. Acquisition of each spectrum requires about 10sec of data collection time and illumination by ~1mW of 785nm laser power, thus enabling the rapid and readily portable nature of this technique.

By expanding the size of the data base, spectral variation due to donor variability was found to be limited sufficiently to allow robust identification of human body fluid types. Several key components of each body fluid have been identified. Molecular vibrational signatures of uric acid, hypoxanthine, protein, and hemoglobin are seen in dried blood SERS spectra; protein, hypoxanthine, and adenine are seen in vaginal fluid spectra; protein, hypoxanthine, and xanthine are seen in semen; and phenylalanine and protein are seen in saliva. These studies intend to show that the SERS spectra of dried blood, vaginal fluid, and semen on various materials such as fabrics, carpet, or glass will have minimal variation and allow identification via the barcode-based PLSDA procedure. Mixture resolution of interest to sexual assault cases (i.e., semen and vaginal fluid, menstrual blood and semen, saliva and vaginal fluid) will be demonstrated.

The quantitative results presented will demonstrate that these most recent advances in the development of SERS for confirmatory identification of trace amounts of body fluids at crime scenes has the potential to be a rapid, sensitive, easy-to-use, portable tool for forensic investigators in the near future.

SERS, Body Fluids, Identification

B185 Optimum Case Detection Limit of the Forensic Luminol Test for Bloodstains

Stephen L. Morgan, PhD, University of South Carolina, Dept of Chemistry & Biochemistry, 631 Sumter Street, Columbia, SC 29208; Brianna M. Cassidy, BS, University of South Carolina, Dept Chemistry & Biochemistry, 631 Sumter Street, Columbia, SC 29208; Zhenyu Lu, BS, University of South Carolina, Dept of Chemistry & Biochemistry, 631 Sumter Street, Columbia, SC 29208; Jennifer P. Martin, BS, University of South Carolina, Dept of Chemistry and Biochemistry, 631 Sumter Street, Columbia, SC 29208; Shawna K. Tazik, BS, University of South Carolina, Dept of Chemistry and Biochemistry, 631 Sumter Street, Columbia, SC 29208; Katherine A. Witherspoon, BS, University of South Carolina, Dept of Chemistry and Biochemistry, 631 Sumter Street, Columbia, SC 29208; Katherine E. Kilgore, 704 Sailclub Road, Hartsville, SC 29550; Stephanie A. DeJong, BS, University of South Carolina, Dept Chemistry & Biochemistry, 631 Sumter Street, Columbia, SC 29208; Raymond G. Belliveau, BS, University of South Carolina, Dept Chemistry & Biochemistry, 631 Sumter Street, Columbia, SC 29208; and Michael L. Myrick, PhD, University of South Carolina, Dept of Chemistry & Biochemistry, 631 Sumter Street, Columbia, SC 29208*

After attending this presentation, attendees and especially crime scene investigators and DNA analysts will have a realistic description, based on systematic experimentation under controlled conditions, of the chemical behavior of luminol during reaction with low levels of blood.

This presentation will impact the forensic science community by providing information concerning the optimum-case Limit Of Detection (LOD) for bloodstains, which could impact interpretation of luminol tests conducted at crime scenes.

Luminol formulations are used by criminologists as a presumptive test for detecting latent bloodstains. The luminol test has been used by forensic investigators to aid in the discovery of bloodstains and to visualize blood spatter for more than 60 years. Many studies have been carried out which explore the luminol Limit Of Detection (LOD) for bloodstains; however, the luminol LOD is still elusive, having detection limits reported which range from100x to 5,000,000x dilute bloodstains. This range in reported luminol LODs stems from lack of experimental control: luminol applied to bloodstains is generally not accurately measured, the blood-luminol response is usually detected qualitatively using human observation, and bloodstain samples were produced without regard to the effect blood dilution has on spreadability. These factors do not allow for accurate determinations of LODs or effective comparisons of blood detection agents. Furthermore, published studies have not quantitatively defined the relationship between important variables involved in the blood-luminol reaction (such as bloodstain dilution, amount of luminol applied, age of luminol solution, etc.) and chemiluminescent response. Knowledge of how the blood-luminol response is affected will increase the utility of luminol, allowing investigators to make educated decisions both in luminol application technique and in luminol response analysis.

An experimental method was designed with heightened variable control, which renders an optimum-case luminol LOD and reveals a linear relationship between bloodstain dilution and chemiluminescent response. Blood solutions ranging from 10,000x to 40,000x were deposited on cotton T-shirt swatches using a patented stain barrier technique. The luminol formulation was applied to bloodstains in complete darkness and the response was measured using a digital Charge-Coupled Device (CCD) camera. Pixel intensity information was extracted from the resulting raw images and a linear relationship was discovered between bloodstain dilution and chemiluminescent response. An optimum-case LOD of approximately 100,000x was calculated.

Luminol, Limit of Detection, Bloodstains

B186 Time-Dependent Loss of Messenger RNA (mRNA) Transcripts From Forensic Samples Analyzed Using Next Generation Sequencing

Katelyn D. Weinbrecht, MS, 1923 S Jackson Avenue, Apt 38K, Tulsa, OK 74107; and Robert W. Allen, PhD, Oklahoma State University, Center for Health Sciences, 1111 W 17th Street, Tulsa, OK 74107-1898*

After attending this presentation, attendees will understand the relationship between mRNA degradation and age outside the body for body fluid stains and how this information may allow for estimating how long a biological sample has been at a crime scene.

This presentation will impact the forensic science community by providing tools with which to estimate how long evidence has been at a crime scene and by possibly improving interval-since-death estimates.

Forensic biology generally has a focus on DNA and the identification of the donor of a DNA sample recovered at a crime scene. Recently, RNA analysis has also demonstrated potential as a worthwhile analyte in the forensic biology laboratory. Applications for RNA analysis include the use of RNA to the identify the tissue source(s) of an evidentiary sample, perhaps assisting in determining the age of a biological sample and in a determining the cause of death through an analysis of expressed genes and how defects in gene expression may have contributed to the death (i.e., a molecular autopsy). Although recent research has indicated many possible forensic applications of RNA analysis, many questions remain concerning the behavior of RNA in degraded and limited samples. Specifically, the need remains for a thorough understanding of the differing patterns and rates of RNA degradation in postmortem and deposited samples.

The purpose of this research was to evaluate mRNA degradation in forensically relevant biological sample types (blood, saliva, semen, and vaginal fluid) utilizing next generation sequencing of fresh and aged samples. By incorporating a panel of synthetic well-characterized RNA sequences of known molar concentration with the initial mRNA preparation, it was possible to quantitatively compare samples stored for various lengths of time up to one year and measure the concentration of different transcripts over time. The mRNA transcripts from tissue-specific markers and those present in all tissue samples were examined. A significant number of tissue-specific transcripts were identified. Specifically, there were 1,449 blood-specific transcripts, 124 saliva-specific transcripts, 211 vaginal fluid-specific transcripts, and 1,712 semen-specific transcripts detected. In addition to the tissue-specific transcripts, there were 1,875 transcripts common to all of the sample types. Both the tissue-specific transcripts and the common transcripts provide an adequate population for the selection of transcripts that disappear over time in a predictable way. Transcripts of both types (tissue-specific and common) decreased in abundance over the one year of storage. Tissue-specific transcripts exhibited varying degradation rates, with times ranging from a rapid disappearance within 30 days of storage at room temperature to remaining stable over the course of one year at room temperature.

The mRNA degradation profiles obtained from this study can be used as a guide to gene expression patterns in different body fluid samples and to basal mRNA degradation rates in samples stored under non-hostile conditions (i.e., room temperature in low light). This guide can be compared to sample storage under conditions that may promote accelerated degradation. Once acceptable candidate genes with predictable degradation rates have been identified and characterized, real-time PCR assays can be developed and implemented more easily in the forensic biology laboratory for routine analysis of casework samples.

mRNA Sequencing, mRNA Degradation, Sample Age

B187 An Evaluation of the Differential Stability of Nucleic Acids in Biological Fluids Compromised by Environmental Exposure

Tiffany R. Layne, BS, 3906 Grovewood Road, Hopewell, VA 23860; Zendra E. Zehner, PhD, VCU School Med/Massey Cancer Center, Dept of Biochemi & Molecular Biology, 1101 E Marshall Street, PO Box 980037, Richmond, VA 23298-0037; and Sarah J. Seashols Williams, PhD, Virginia Commonwealth University, Dept of Forensic Science, PO Box 843079, Richmond, VA 23284-3079*

After attending this presentation, attendees will better understand how much of an effect the environment has on evidence and biological material through a discussion of relative degradation rates of DNA, messenger RNA (mRNA), and microRNAs (miRNAs). This presentation will also increase awareness of RNA use in the forensic community and promote research in novel body fluid identification methods.

This presentation will impact the forensic science community by clarifying relative stabilities between RNAs and DNA within the same sample and the stability of RNA for body fluid identification purposes.

The visualization, presumptive, and confirmatory tests used for body fluid identifications in forensic casework have remained static for many years. This is problematic because many of these tests are known to yield false positive results with other biological fluids, foods, or chemicals. Recent work in the forensic science field has explored RNAs for a molecular-based, forensic body fluid identification method. Many researchers have assessed mRNA to identify body fluids. While these research studies provide good evidence for mRNA as being useful in body fluid identification, some research has provided unsupportive evidence and thus mRNA analysis has been slow to catch on for casework. The miRNAs are small RNAs that have the ability to suppress translation of mRNA into proteins and are shorter in length than mRNAs. Because of these advantages and the remarkable stability observed by the species, they are also being considered as markers for body fluid identification. This study evaluated the relative stability of DNA, RNA, and miRNAs in the same samples under conditions mimicking an outdoor crime scene.

Samples of blood, urine, semen, and saliva were placed in an environmental chamber for defined periods of time corresponding from 24 hours to 14 days during a Virginia summer. The environmental chamber manages the irradiance, air temperature, and humidity for a more controlled assessment of sample degradation. DNA and RNA were isolated from each stain, and quantitative Polymerase Chain Reaction (qPCR) for DNA and Real-Time (RT) qPCR for RNA and miRNAs was performed. Expression levels were calculated relative to the positive untreated control samples. DNA stability was evaluated using both standard TPOX and "mini" length primers for the Short Tandem Repeat (STR locus) TPOX. Both mRNA and miRNA expression were evaluated using GAPDH and/or ACTB, and Let-7g, respectively.

The miRNA expression was not significantly impacted by treatment in the environmental chamber, unlike the impacted levels of DNA and mRNA. When measuring miRNA stability, Let-7g levels were not significantly different from the untreated control levels for all four body fluid samples. The DNA and mRNA data showed how environmental effects can greatly degrade biological material after exposure. The data from this project drives home the environmental effects on biological material, clarifies differential stability of the nucleic acids, and, consequently, can provide the practitioner with options for analysis workflows in compromised samples.

RNA, Degradation, Body Fluid Identification

B188 Obtaining Significant Powers of Individual Discrimination From Hair Shaft Proteins

Glendon Parker, PhD, Protein-Based Identification Technology, 4421 Ashwood CMN, Fremont, CA 94538; Deon Anex, PhD, Lawrence Livermore National Laboratory, 7000 East Avenue, Livermore, CA 94550; Katelyn Mason, PhD, Lawrence Livermore National Laboratory, 7000 East Avenue, Livermore, CA 94550; and Bradley Hart, PhD, Lawrence Livermore National Laboratory, 7000 East Avenue, Livermore, CA 94550*

After attending this presentation, attendees will better understand the potential role of protein in obtaining quantifiable statistically based powers of discrimination from biological samples.

This presentation will impact the forensic science community by explaining how the past few decades have seen the impact of nuclear and mitochondrial DNA typing on forensic science. This presentation introduces a third identifying method based on protein typing. Genetically variant peptides from hair shafts can be used to infer the status of **Single Nucleotide Polymorphism** (SNP) loci in a subject's genome.

If DNA is not present in biological samples collected as evidence, the options for the forensic investigator are limited. Protein is considerably more stable and abundant than DNA by many orders of magnitude. Genetic variation found in protein encoding genes, in the form of non-synonymous SNPs (nsSNPs), results in changes in protein amino acid sequence. Identifying and detecting these single amino acid polymorphisms in proteins therefore allows genetic content of a subject's DNA to be inferred, allowing peptides to be a surrogate for absent or unusable DNA.

To demonstrate this approach, a thorough examination of the protein population in hair shafts was conducted. Hair shafts are a poor source of nuclear DNA, yet are present in many forensic and bioarchaeological contexts. Methods were developed to identify and maximally detect peptides in hair shafts that retain genetic information. First, hair is milled and extracted with high levels of reductant, urea, and mass spectrometry-compatible detergent. The proteins are then alkylated and digested with trypsin to produce a highly complex mixture of peptides. These peptides are then resolved by high-pressure liquid chromatography and analyzed by tandem mass spectrometry. The resulting mass spectra are then matched to peptide sequences and a subset of peptides containing single amino acid polymorphisms are identified.

Genetically Variant Peptides (GVPs) have been characterized that correspond to 43 genetic nsSNP loci. In applying the product rule, dependency between loci within the gene boundary and full independence beyond it were assumed for now. When the product rule is applied, these GVP profiles result in powers of discrimination up to 1 in 5.4 million in the European population. The efficacy of each GVP in inferring the genetic status of corresponding genomic SNPs can be directly measured when compared to direct Sanger sequencing of subjects' DNA. Out of 608 inferences made, only 12 were false positive assignments, a greater than 98% true positive rate. Importantly, false positives clustered around a limited number of less-predictive GVPs. When poorly performing GVPs are eliminated from the analysis, the false positive rate decreases to less than 1%. When using SNP allelic frequencies from the African population, the GVP profiles were considerably less common by a factor of up to 29,000. The resulting likelihood scores, including those from European and African subjects, are a source of biogeographic information that range more than seven orders of magnitude across the samples tested. This indicates that peptides have the potential to provide information about the genetic background of the hair donor. These numbers have been obtained by applying the equivalent of less than 2mm of hair shaft to mass spectrometric analysis.

Application of this methodology to forensic fieldwork samples requires two milestones to be achieved: information needs to be obtained from a single hair, and dependence patterns of hair shaft proteins need to be fully elucidated. Both of these projects are under active investigation. Expansion of these methodologies beyond hair proteins to include alternative tissue types such as teeth, bone, and skin cells is critical to expanding the scope and application space for this novel approach to human forensics.

Protein Typing, Hair, Proteomics

B189 Using DNA Barcoding to Assess DNA Viability in Plant and Insect Fragments Isolated From Forensic Soil Samples

Kelly A. Meiklejohn, PhD, ORISE/FBI Laboratory, 2501 Investigation Parkway, Quantico, VA 22204; Megan L. Jackson, BS, 1 Joplin Court, Stafford, VA 22554; Jack Hietpas, PhD, FBI-ORISE, 2501 Investigation Parkway, Quantico, VA 22135; Libby A. Stern, PhD, FBI Laboratory - CFSRU, 2501 Investigation Parkway, Quantico, VA 22135; and James M. Robertson, PhD, CFSRU, FBI Laboratory, 2501 Investigation Parkway, Quantico, VA 22135*

After attending this presentation, attendees will understand the fundamentals of DNA barcoding and whether the DNA of biological fragments collected in forensic soil samples is viable toward molecular analysis.

This presentation will impact the forensic science community by providing an assessment as to whether the individual biological fragments commonly present in soil samples could provide additional information for provenance and thus be implemented in casework.

Every year, debris samples are submitted to forensic laboratories as evidence, but the insect and plant materials commonly found in such samples are rarely analyzed. This is despite the fact that individual insect and plant materials could add to the characterization of the sample that is provided by inorganic analysis.[1] In addition, biological material could provide information for soil geo-attribution, since insects and plants inhabit specific ecosystems. Seasonal distribution of plant and insect material will provide additional information for the sample. One reason such biological material is not analyzed is because microscopic identification is not straightforward, especially for examiners who not appropriately trained. Different individual specimens may present similar morphologies that are impossible to distinguish and there may be fragments instead of the whole insect or plant as well as specimens at different developmental stages. In these circumstances, using DNA for identification is an attractive alternative approach as DNA is present in all biological tissues.

Species-level identification is possible by using sequence data. DNA barcoding, which utilizes a standardized short sequence of DNA, typically 400–800 base pairs in length, is now a commonly accepted forensic approach for molecular identification.[2,3] The barcode sequence of the DNA from the item of interest is compared with sequences in public databases for classification of the sample. The mitochondrial Cytochrome Oxidase subunit 1 (CO1) gene has been adopted as the standard barcoding region for insect identification as it has a fast mutation rate and is found in high copies within tissues.[4] Two plastid regions (an organelle found exclusively in the cells of plants and algae), rbcL and matK, have been adopted as the core barcode regions for land plants as CO1 evolves too slowly to facilitate species-level discrimination of plant species.[4]

Using surface soil samples collected from various locations in Virginia with varied geology and ecohabitats to represent soil evidence associated with shoes and digging tools, the following will be discussed: (1) what types of plant and insect fragments are commonly recovered with surface soil samples; (2) whether such fragments contain viable DNA; and, (3) whether the appropriate DNA barcode regions could be amplified and sequenced using traditional Sanger methods. Ten insect and ten plant fragments were collected from each site (n=200). Various commercial kits for DNA extraction from the insect and plant material were compared. The results of these kits as well as the use of degenerate primers for COI, rbcL, and matK will be presented along with the success rate of the published barcoding protocols. Issues encountered when searching the data against two public databases, the National Center for Biotechnology Information (NCBI) and the Barcode of Life Database (BOLD) will be described in order to assess congruence and taxonomic identification.

Forensic Soil Samples, Species Identification, DNA Barcoding

B190 Evaluation of a 13-Loci Short Tandem Repeat (STR) Multiplex System for *Cannabis Sativa* Genetic Identification

Rachel M. Houston, BS, 3505 Snidow Drive, Plano, TX 75025; Sheree R. Hughes-Stamm, PhD, Sam Houston State University, Dept of Forensic Science, Huntsville, TX 77341; and David A. Gangitano, PhD, Sam Houston State University, 13906 Paradise Valley Drive, Houston, TX 77069*

After attending this presentation, attendees will understand the basic principles behind using an STR multiplex method for individualizing marijuana samples.

This presentation will impact the forensic science community by providing an STR panel that could not only assist law enforcement agencies in verifying legal marijuana products but also aid in the linkage of illegal cases. This method could also serve as an additional tool to previously established marijuana profiling programs used in federal agencies such as the United States Customs and Border Protection (CBP) and the Drug Enforcement Administration (DEA).

Marijuana (*Cannabis sativa*) is the most commonly used illicit substance in the United States. Although the federal government considers marijuana a Schedule I substance, it has become legalized for recreational use in four states (Colorado, Washington, Oregon, and Alaska). As a result of legalization, law enforcement faces a unique challenge in tracking and preventing the flow of legal marijuana to states where it is illegal. Moreover, there is significant traffic of illegal marijuana from Mexico. When identifying marijuana for legal purposes, the Scientific Working Group for the Analysis of Seized Drugs (SWGDRUG) recommendations require the confirmation of THC via Gas Chromatography/Mass Spectroscopy (GC/MS), the microscopic confirmation of the presence of cystolithic hairs, and a positive Duquenois-Levine color test.[1] These tests are sufficient for prosecuting an individual for possession of marijuana but do not provide any meaningful intelligence as to the origin or individualization of the plant; however, there are many methods that can be used to individualize and determine the origin of a marijuana sample. These methods include, but are not limited to, palynology, chemical profiling, Isotope Ratio Mass Spectrometry (IRMS), and DNA analysis.[2-6] DNA has been shown to provide higher resolution for the individualization of marijuana plants as compared to the other techniques.[7]

The development of a validated molecular method such as STRs could aid in the individualization of cannabis samples as well as serve as an intelligence tool to link multiple cases (e.g., illegal traffic at the United States-Mexico border). For this purpose, a modified STR multiplex method was optimized and evaluated according to the International Society for Forensic Genetics (ISFG) and the Scientific Working Group on DNA Analysis Methods (SWGDAM) guidelines.[8] A new quantitative Polymerase Chain Reaction (qPCR) method was developed to accurately quantitate the amount of cannabis DNA extracted. A sequenced allelic ladder was also designed to accurately genotype 199 *C. sativa* samples from 11 seizures provided by a federal agency.

Distinguishable DNA profiles were generated from 127 samples that yielded full STR profiles, and four duplicate genotypes within seizures were found. From the analysis of STR profiles and the lack of clonal material, it can be concluded that the analyzed cannabis samples, most likely from Mexico, were propagated from seeds. The combined power of discrimination of this multi-locus system is 1 in 70 million with a sensitivity of 0.25ng of template DNA. The 13-STR panel was found to be species-specific for *C. sativa*; however, non-specific peaks were generated for *Humulus lupulus* (Hops). Phylogenetic analysis and case-to-case pairwise comparison of 11 cases using F_{ST} as genetic distance revealed the genetic association of four groups of cases. Moreover, due to their genetic similarity (common origin), a subset of samples (*N*=97) was found to form a homogeneous population in Hardy-Weinberg and linkage equilibrium. Using this homogenous population, a reference cannabis population database with associated allele frequencies for forensic purposes was developed.

In conclusion, the results of this research demonstrate the applicability of this 13-loci STR system not only in associating cannabis cases for intelligence purposes, but also in potentially detecting the presence of plant material generated via clonal propagation.

B191 Development of a High Resolution Real-Time Polymerase Chain Reaction (PCR) Melt Assay for Identifying "Legal High" Plant Material

Alicia Quinn, BS, 120 Stoney Meadow Lane, Madison Township, PA 18444; and Kelly M. Elkins, PhD, Towson University, Chem Dept & Forensic Science Program, 8000 York Road, Towson, MD 21252*

After attending this presentation, attendees will better understand plants that endogenously produce chemicals used as "legal highs," how genetic targets can be probed using PCR, and how "legal highs" can be identified using high-resolution melt assays.

This presentation will impact the forensic science community by providing results of the development of a multiplex to probe several "legal high" plant species as well as specificity, reproducibility, selectivity, and sensitivity data for the singleplex assays. This study presents assays that could help forensic laboratories identify trace quantities of plant material in comingled samples.

Mixture analysis has been a cornerstone of human DNA typing methods for several years. Forensic laboratories focus a significant portion of their caseload on detecting and identifying controlled substances and new drugs of abuse. The interpretation of trace material is complicated by the fact that the quantity of recoverable material can fall below the detection limits of instrumental methods. While microscopy is used to identify botanical material, this method has limitations when only trace material is present. Similarly, Gas Chromatography/Mass Spectrometry (GC/MS) is used to identify the active drug compounds contained in the plant material when sufficient material is present for detection and identification. As PCR amplifies the extracted genetic material, it has the advantage of detecting trace or low-template DNA. High resolution PCR melt assays have been developed to detect and identify four plant species: *Cannabis sativa* (marijuana), *Papaver somniferum* (poppy), *Ipomoea purpurea* (morning glory), and *Datura stramonium* (jimson weed). Marijuana and poppy are the two most prevalent internationally abused herbal highs; jimson weed and morning glory can be found in gardens and along roadsides. Reports have indicated that users consume the seeds or plant material whole or via teas or smoking.

To differentiate the plants, PCR primers specific for each plant were designed using public genome data from the National Center for Biotechnology Information (NCBI) and evaluated uniqueness using the Basic Local Alignment Search Tool (BLAST). Each set of PCR primers was designed to produce an amplicon from the plant of interest with a specific melt temperature that differs from amplicons produced with primers for the other plants. DNA was extracted from plant and seed material using the QIAGEN® DNeasy® Plant Mini Kit and primers were obtained from IDT. Using the Bio-Rad iTaq™ Universal SYBR® Green Supermix, the primers were tested for specificity, selectivity, sensitivity, and reproducibility in singleplex reaction assays. Agarose gel electrophoresis was used to confirm production of PCR amplicons of the designed sizes. Progress in multiplexing primer sets to simultaneously detect one or more of the species using an LCGreen mastermix will also be presented. The PCR melt assay is an inexpensive, quick, and specific method to detect and identify genetic material derived from "legal highs." It is expected that the assay could be employed by forensic laboratories to detect and identify "legal highs" in the current international drug market.

DNA, PCR, High-Resolution Melt

B192 Epigenetic-Aging-Signature — The Future?

Athina Vidaki, PhD, King's College London, 150 Stamford Street, Franklin Wilkins Bldg, London SE1 9NH, UNITED KINGDOM; Anastasia Aliferi, King's College London, 150 Stamford Street, Franklin Wilkins Bldg, London SE1 9NH, UNITED KINGDOM; David Ballard, PhD, King's College London, 150 Stamford Street, London SE1 9NH, UNITED KINGDOM; Leon Barron, PhD, King's College London, 150 Stamford Street, Franklin Wilkins Bldg, London SE1 9NH, UNITED KINGDOM; and Denise Syndercombe Court, PhD, King's College London, 150 Stamford Street, London SE1 9NH, UNITED KINGDOM*

After attending this presentation, attendees will better understand the potential of applying epigenetic markers in forensic age prediction.

This presentation will impact the forensic science community by proposing a quantitative Next Generation Sequencing (NGS) approach in estimating chronological age and by demonstrating this approach's accuracy, reproducibility, and applicability in a set of whole blood samples and stains.

Estimating an individual's biological age can be of great use when studying ageing or predicting disease susceptibility; however, estimating someone's chronological age would also be of significant value in criminal investigations. In cases in which there are no suspects or eyewitnesses available to provide investigative leads, predicting a bloodstain donor's age could eliminate potential suspects. There are various chemical or biological methods that have been proposed for age estimation in bones, teeth, or other tissues, such as lead accumulation, protein modifications, telomere length, and mitochondrial DNA (mtDNA) deletions; however, they all suffer from limitations including poor accuracy. Most of these methods are more likely to suggest an age group (generation) rather than accurately predicting age, which restricts their applicability in forensic casework.

Epigenetic analysis has been reported in the literature as an alternative or supplementary method for age prediction since DNA methylation of cytosines followed by guanines (known as CpG sites) is known to be one of the mechanisms responsible for cell differentiation and the cellular response to aging. Various genome-wide DNA methylation analyses investigating thousands of CpG sites at the same time have revealed a substantial decrease in global DNA methylation levels with advancing age. As a result, various age prediction models using a subset of these sites have recently been proposed for demonstrating good accuracy (average prediction error <5 years); however, due to the potentially low quantity and quality of crime scene samples, genome-wide approaches are not applicable in forensic genetics. Therefore, there is a need to develop methodologies that analyze only a few CpG sites without compromising accuracy and sensitivity.

In this study, hundreds of previously reported CpG sites were carefully selected from the literature as potential age-associated markers, and a dataset comprised of ~2000 whole blood samples was created using publicly available DNA methylation data. In an attempt to identify a subset of these markers to be included in the epigenetic-aging-signature, linear regression analysis was applied. Utilizing only the CpG sites showing the strongest association with age, an age-prediction model was generated using Artificial Neural Networks (ANN). The potential of ANN models in predicting complex characteristics has been previously explored showing great accuracy and reproducibility. Predictions were highly accurate for both the verification and blind tests. To apply this epigenetic aging signature in forensic casework, a protocol based on bisulfite conversion and sequencing using Illumina's® MiSeq® platform was developed and optimized using artificially made DNA standards of known methylation levels. Validation experiments revealed that the method is highly sensitive, accurate, and reproducible; therefore, the model's prediction accuracy was further investigated by analyzing a set of whole blood samples and mock casework samples. Following treatment with sodium bisulfite and amplification of the fragments containing the proposed CpG sites in multiplex bisulfite PCR reactions, libraries were prepared using an optimized NGS protocol. The resultant prediction accuracy was not as high as in the ANN model; however, it is believed that further optimization of the method could reduce prediction errors.

These findings provide a new quantitative tool for estimating chronological age in crime scene bloodstains, which, together with current methods, could provide new investigative leads in criminal cases. Future research will be able to expand on these results by identifying new markers, investigating population differences, or extending to different tissues.

Age Prediction, DNA Methylation, Next Generation Sequencing

B193 A Raman "Spectroscopic Clock" for Bloodstain Age Determination: The First Week After Deposition

Kyle C. Doty, BS, 2165 Robinwood Avenue, Schenectady, NY 12306; Gregory McLaughlin, MS, 100 Manning Boulevard, Albany, NY 12203; and Igor K. Lednev, PhD*, University at Albany, State University of New York, 1400 Washington Avenue, Albany, NY 12222*

After attending this presentation, attendees will better understand how Raman spectroscopy, coupled with 2D Correlation Spectroscopy (2D CoS) and chemometrics, can be used to analyze bloodstains, link known molecular changes with spectral variations, and predict the Time Since Deposition (TSD) for up to one week.

This presentation will impact the forensic science community by introducing a unique non-destructive method for confirmatory blood identification and bloodstain age prediction, accompanied by a statistical level of confidence, all of which could potentially be performed at the crime scene.

The identification of a body fluid stain is an important and necessary aspect of many forensic investigations. For blood in particular, knowing the TSD is highly desired in forensics, but it can be extremely complicated to accurately determine in practice. Although there have been numerous attempts to solve this problem using a variety of different techniques, currently no established, well-accepted method exists. Since the amount of suspected blood evidence may be miniscule, it needs to be preserved and analyzed efficiently. Therefore, a non-destructive method to competently identify human blood and predict the TSD would be highly valuable. Raman spectroscopy is a technique that has the potential for both non-destructive confirmatory identification of blood and for detecting molecular changes over time.

Raman spectroscopy has proven to be a versatile and effective analytical technique for numerous forensic applications, including the identification of drugs, explosives, gunshot residue, inks, paints, and dyes. Raman analysis often requires no sample preparation, is typically non-destructive, and has the ability to analyze microscopic amounts of sample. This technique is based on the detection of light that is inelastically scattered by a sample upon irradiation from a monochromatic light source. A Raman spectrum contains numerous distinctive bands that correspond to specific molecular vibrational modes. For blood in particular, Raman spectra provide rich detail and has been the subject of analysis in many forensic studies already. Popularity of Raman spectroscopy has been growing in forensic science, especially due to recent advancements in portable instrumentation and the breadth of both current and potential applications.

For this study, a Raman spectroscopic approach was developed for determining the age of bloodstains up to one week old. Raman spectroscopy, along with 2D CoS and statistical modeling, was used to analyze fresh bloodstains at ten time points under ambient conditions. The results of the 2D CoS indicate a high correlation between multiple Raman bands and the age of a bloodstain. A regression model was built to provide quantitative predictions of the TSD, with a cross-validated root mean squared error of 0.13 and an R^2 of 0.97. It was determined that a "new" (one hour old) bloodstain could be easily distinguished from bloodstains at other ages, which is very important for forensic science in helping to establish the relevant association of multiple bloodstains. Additionally, all bloodstains were identified as blood by comparing the measured spectra to multidimensional body fluid spectroscopic signatures. These results demonstrate that Raman spectroscopy can be used as a non-destructive analytical tool for discriminating between bloodstains on the scale of hours to days. This approach shows promise for immediate practical use in the field to predict the time since deposition with a high degree of accuracy.

This project was supported by the National Institute of Justice, Office of Justice Programs, United States Department of Justice. The opinions, findings, and conclusions or recommendations expressed in this presentation are those of the authors and do not necessarily reflect those of the Department of Justice.

Raman Spectroscopy, Bloodstain Age, Chemometrics

B194 Investigations on the Use of Tissue MicroRNA Markers to Correlate Bloodstains With Wounds for Bloodstain Pattern Analysis

Donald J. Johnson, MS, California State University, Los Angeles, School of Criminal Justice and Criminalistics, 5151 State University Drive, Los Angeles, CA 90032; David Raymond, PhD, California State University, Los Angeles, Dept of Mechanical Eng, 5151 State University Drive, Los Angeles, CA 90032; and Ray de Leon, PhD, School of Kinesiology and Nutritional Science, California State University, Los Angeles, 5151 State University Drive, Los Angeles, CA 90032*

After attending this presentation, attendees will have an understanding of: (1) current limitations in bloodstain pattern analysis; (2) the probative value of wound tissue in bloodstains; and, (3) the effectiveness of micro RNA assays to identify trace quantities of wound cells in bloodstains and determine the wound-of-origin.

This presentation will impact the forensic science community by demonstrating that molecular markers can reveal information about the circumstances surrounding the deposition of blood evidence, namely the wound-of-origin. Otherwise indistinguishable and/or non-specific bloodstains can be further characterized by use of this technique. The implementation of the technique may enhance the work of forensic investigations and the administration of justice.

Certain bloodstain patterns can indicate the cause of the bloodshed. For example, an "arterial" bloodstain pattern indicates a breach to the arterial circulatory system; however, many patterns can be created by more than one mechanism. A pattern of several circular bloodstains on the floor, for example, could be the result of a minor injury or a life-threating/fatal wound. During the course of a homicide investigation, investigators may find blood from the victim or suspect, but the blood is found where one might expect to find victim's or suspect's blood for reasons other than the crime. The finding is further problematic in that the blood is in low quantities and in the form of a non-specific bloodstain pattern. The relationship of the blood to the crime then comes into question because of the circumstances of the case and the uninformative pattern of the blood. The blood may be evidence of the crime or the blood may be a coincidental finding unrelated to the crime. The finding may be used against a suspect or defendant, but the suspect/defendant may have a plausible alternate explanation for the finding; however, current forensic methods in this situation are greatly limited in the ability to test the different explanations and determine the correct circumstances under which the blood was shed.

In several homicide cases, evidentiary bloodstains with particular wounds based on the histological identification of wound tissue in the stains were able to be correlated; however, the finding of discernible pieces of wound tissue in bloodstains is rare in cases where the question is the bodily source of the stain, It is hypothesized that evidentiary bloodstains may contain trace quantities of wound cells, which can serve as markers to identify the specific wound or wound site from which the bloodstains originated and thus provide a means to answer questions as to the cause and significance of otherwise ambiguous blood evidence.

It has been reported that bloodstains can contain additional information about their origin in the form of wound cells. Using an animal model, bloodstains from a gunshot wound to the head were distinguished from bloodstains resulting from a gunshot wound to the chest by testing the stains for a brain micro RNA marker. The head shot and chest shot spatter patterns and the two sets of tested bloodstains were otherwise indistinguishable. Whereas proof-of-concept was achieved with the shooting experiments, the question then became whether the technique would be successful with bloodstains from injuries produced by less force; specifically, sharp force injuries. Hence, a proof-of-concept study was conducted on the use of micro RNA tissue markers to detect wound cells in blood drops resultant of stab wounds.

Specifically, investigations were conducted on the rat liver micro RNA marker, rno-mir-122-3p, with the QIAGEN® miScript® System and real-time Polymerase Chain Reaction (PCR) analysis. Intact rat carcasses were stabbed manually and with a mechanical device. Scalpel blades were used to stab the liver through the skin of the rat carcasses, and the blood on the scalpel blades tested positive for rno-mir-122-3p, whereas blood on the scalpel blade used to stab the lung through the chest wall tested negative for rno-mir-122-3p. Additionally, blood drops shed externally from the liver stab wounds tested positive for liver cells. The amount of the marker/cells in the stains appeared to be related to the sequence of the blood drops and the velocity of the blade. This research illustrates that molecular markers can reveal information about the circumstances surrounding the deposition of blood evidence, namely the wound-of-origin. The implementation of this technique may enhance forensic investigations and the administration of justice.

MicroRNA, Wound-of-Origin, Bloodstain Pattern Analysis

B195 Examination of Plastic Shopping Bags Using Attenuated Total Reflectance/Fourier Transform Infrared Spectrometry (ATR/FTIR)

Walter F. Rowe, PhD, George Washington University, Department of Forensic Science, 2100 Foxhall Road, NW, Washington, DC 20007*

After attending this presentation, attendees will understand how to obtain ATR infrared spectra from polymer films with high signal-to-noise ratios. Attendees will also understand the varied compositions of common plastic shopping bags and the capability of ATR/FTIR to differentiate shopping bags from different sources.

This presentation will impact the forensic science community by providing trace evidence examiners with knowledge of the composition of a common type of polymer material that may occur as forensic evidence. The presentation will also emphasize the value of paying attention to low levels of additives in polymeric products.

Plastic bags may appear in criminal investigations as packaging for many different types of evidence; however, only three publications have dealt with the forensic examination of plastic bags. Roux et al. analyzed a number of different types of bags (e.g., freezer bags, vegetable storage bags, sandwich bags, and general storage bags) purchased in Australia and in Asian countries.[1] Infrared spectrometry proved (along with visual examination) to be the most useful method for discriminating bags from different sources. Causin et al. examined shopping bags obtained from supermarkets in the Venice, Italy, area, using infrared spectrometry, thickness measurements, and differential scanning calorimetry.[2] The infrared spectra of the shopping bags fell into three categories: (1) pure polyethylene; (2) polyethylene containing calcium carbonate ($CaCO_3$); and, (3) polyethylene with a carbonyl stretch at 1740cm^{-1}. Hashimoto et al. analyzed plastic bags specially prepared by Japanese manufacturers using X-ray diffraction, infrared spectrometry and optical microscopy.[3]

This research used ATR/FTIR to examine shopping bags used in the United States and compare the results with previously published work.[1-3] Principal Component Analysis (PCA) and Linear Discriminant Analysis (LDA) were applied to the data to see if these methods yielded greater differentiation of the spectra compared to simple visual comparison. Forty different plastic shopping bags were obtained in the Washington, DC, area from supermarkets, department stores, restaurants, and hardware stores. ATR/FTIR spectra were obtained from five different non-printed areas on each bag. The ATR/FTIR spectra were obtained using a minimum of four layers of bag material to insure high signal-to-noise ratios to facilitate detection of the peaks of minor constituents. The spectra were scanned from 525cm^{-1} to 4,500cm^{-1} at 4cm^{-1} resolution; 128 scans were collected for each spectrum.

The shopping bags were found to be homogeneous and comprised of polyethylene, usually with an inorganic filler. Most of the shopping bags were found to contain $CaCO_3$. As Causin et al. found in the shopping bags they examined, the concentrations of $CaCO_3$ showed considerable variation.[2] Two of the bags contained talc and one bag contained both $CaCO_3$ and talc. Talc and $CaCO_3$ were confirmed by X-ray diffraction.

The spectral data from 525cm^{-1} to 1,800cm^{-1} were analyzed by PCA. Prior to PCA, the ATR /TIR spectra were scaled by setting the absorbances of the most intense peak of polyethylene to the same value. Some of the scaled spectra had significant baseline offsets; these were removed by taking the first derivative of the spectral data. Finally, the first-derivative data were autoscaled prior to PCA. The first factor extracted by PCA represented the quantity of $CaCO_3$ present in the bags, while the second factor represented the quantity of talc. LDA was performed using the extracted principal components and placed the ATR/FTIR spectra in seven groups with 100% accuracy.

B196 X-Ray Powder Diffraction (XRPD) Method Development and Validation for the Identification of Counterfeit Pharmaceuticals

Mark R. Witkowski, PhD, U.S. Food & Drug Administration, Forensic Chemistry Center, 6751 Steger Drive, Cincinnati, OH 45237; Nicola Ranieri, BS, 6751 Steger Drive, Cincinnati, OH 45237; JaCinta Batson, MS, FDA's Forensic Chemistry Center, 6751 Steger Drive, Cincinnati, OH 45237 ; Lauren L. Richards-Waugh, PhD, Marshall University, 1401 Forensic Science Drive, Huntington, WV 25701; and Kelsey M. DeWitt, BS, 8 Pyramid Drive, Apt 822, Huntington, WV 25705*

After attending this presentation, attendees better understand the method development and validation for analyzing suspect counterfeit pharmaceuticals with the Bruker® D2 PHASER desktop X-ray powder diffractometer. Attendees will also understand how this method of analysis could be beneficial compared to other popular methods such as Fourier Transform Infrared (FTIR).

This presentation will impact the forensic science community by providing information on an additional method of analyzing and distinguishing counterfeit pharmaceuticals from authentic pharmaceuticals.

Counterfeit pharmaceuticals are illegally manufactured and widely distributed throughout the world, which is a major threat to public health. Counterfeit pharmaceuticals are unapproved and unregulated products which may contain dangerous or harmful ingredients or insufficient amounts of the Active Pharmaceutical Ingredient (API) the patients require to stabilize or improve their health.[1] Historically, counterfeit pharmaceuticals have been found to not contain the correct amount of API, to contain a different API, no API, or the incorrect excipients within the counterfeit product.[1,2] Fast, easy-to-use, and reliable techniques are required to screen and identify a suspected counterfeit product from an authentic product, ensuring the safety of the public's health.[2]

XRPD is a technique often used in forensic science to analyze various types of trace evidence. XRPD has been shown to be a useful technique in the analysis of suspect counterfeit pharmaceutical products.[3] Previous work has shown that the X-ray diffraction spectra of authentic products can be compared to those of suspect counterfeit products to differentiate authentic products from counterfeit products. In some cases, this technique can be used to determine the presence or absence of an API or other excipients within a dosage form, and ascertain whether the correct API is present within that dosage form.[1] This study describes the method development for analyzing authentic pharmaceutical solid-dosage forms, APIs, and excipients to be used to identify suspect counterfeit pharmaceuticals using the Bruker® D2 PHASER diffractometer at the Food and Drug Administration's Forensic Chemistry Center (FCC).

First, an XRPD spectral library was built by analyzing excipients and active pharmaceutical ingredient standards using the Bruker® D2 PHASER instrument. Next, authentic pharmaceutical dosage forms were analyzed and compared to the corresponding API and excipient standard XRPD spectra to determine if the standards could be observed within the dosage form pattern. The XRPD spectral variability between authentic tablets and different lots of a product were determined to assess the product changes between tablets and lot numbers of the product. Counterfeit dosage forms were then analyzed and compared to the authentic dosage form XRPD spectra to determine if the counterfeit products could be differentiated from the authentic products. The information provided in the United States Pharmacopeia (USP®) General Chapter <941> was used as a guide for the method validation.[4]

The APIs, excipients, and authentic pharmaceutical products chosen for the method development were based on pharmaceutical products for which the FCC has known examples of counterfeits. XRPD spectra of the APIs and excipients were collected first, then the authentic dosage forms were collected. A series of experiments were conducted to determine the optimum sampling and measurement parameters for the standard powders (APIs, excipients) and the dosage forms. The initial results showed that peaks in the XRPD spectra of the APIs were not easily distinguishable in the authentic dosage form XRPD spectra. This was determined to be attributed to the concentration of the API present in the dosage forms and the manipulation of the API during the manufacturing process. The manipulation of the API during the manufacturing process may change the crystallinity of the API in such a way that the XRPD spectrum of the API in the dosage form is different than that of bulk powder API. Based on this result, absence/presence of API could not be used to distinguish authenticity.

Instead of looking for the absence/presence of the API to determine authenticity, it was found that overall differences in the counterfeit formulation compared to the authentic product formulation could be used to determine authenticity. It was also determined that counterfeit products contain various excipients with different crystalline structures than the authentic product. In cases where the counterfeit tablet formulation was similar to the authentic product, the difference in the crystalline structure of the excipients in the counterfeit products resulted in peak shifts greater than 0.2° at the 2θ-diffraction angle for a given peak in the XRPD spectra. This would indicate a counterfeit product.[4] This method can be used to distinguish counterfeit pharmaceuticals from authentic pharmaceuticals by looking at the overall XRPD spectral differences (additional peaks, missing peaks, and peak shifts). This presentation will discuss the method development and validation work conducted at the FCC in using XRPD to differentiate counterfeit pharmaceutical products from authentic products.

The mention of specific products/instruments in this presentation is for information purposes only and does not constitute an endorsement by the Food and Drug Administration and/or the Forensic Chemistry Center.

B197 Microextraction Capsules (MEC): A New Direction in Green Analytical and Forensic Sample Preparation

Abuzar Kabir, PhD, Florida International University, 11200 SW 8th Street, AHC4-215, Miami, FL 33199*

After attending this presentation, attendees will better understand the fabrication, working principle, and advantages of MEC in preparing different analytical, environmental, toxicological, pharmaceutical, food, and forensic samples for chromatographic separation and identification.

This presentation will impact the forensic science community by educating attendees interested in analyzing trace organic analytes in various sample matrices and also has the potential to offer a paradigm shift approach in sample preparation by complete elimination of time-consuming, error-prone, and labor-intensive sample pretreatment steps (e.g., filtration, protein precipitation, centrifugation, etc.) from the sample preparation exercises.

Following the sustained demand for establishing the principle of Green Analytical Chemistry (GAC) in all aspects of analytical processes, the current trend in sample preparation inevitably favors miniaturization of the extraction device to minimize sample volume requirement, to reduce or eliminate organic solvent consumption and to minimize the amount of waste generated in the sample preparation process. Due to the high consumption of toxic and hazardous organic solvents and other shortcomings in major sample preparation techniques, including Liquid-Liquid Extraction (LLE) and Solid Phase Extraction (SPE), a number of miniaturized and green sample preparation techniques such as Solid Phase Microextraction (SPME), Stir Bar Sorptive Extraction (SBSE), Thin Film Microextraction (TFME), Microextraction by Packed Sorbent (MEPS), Fabric Phase Sorptive Extraction (FPSE) have emerged during last few decades.[1-5] Among others, these techniques are environment friendly, do not require a high volume of samples, and are fast and efficient.

Despite all the advances in sample preparation technologies, most of the new generation sample preparation techniques cannot handle real-life analytical, environmental, toxicological, pharmaceutical, food, and forensic samples which often contain high volumes of particulates, debris, biomasses, and other matrix interferents and unavoidably require a sample pretreatment process (e.g., filtration, centrifugation, protein precipitation, etc.). Oftentimes, this sample pretreatment/cleaning step leads to significant analyte loss.

MECs are designed to completely eliminate the sample pretreatment/clean-up step from the sample preparation protocol.[6] MEC utilizes a porous tubular polypropylene membrane with 0.2µm pore size and a 5.5mm internal diameter to encapsulate sol-gel hybrid organic/inorganic sorbent in the form of monolithic bed or spherical particles. The porous membrane allows easy permeation of an aqueous sample containing the target analyte(s) while protecting the sorbent from being contaminated. A magnetic metal rod implanted into the MEC allows spinning of the device when placed on a magnetic stirrer and diffuses the sample matrix for fast analyte-sorbent interaction. Thus, high loading of sol-gel sorbent provides high sample capacity for target analyte(s), fast extraction kinetics due to the sponge-like porous architecture of sol-gel sorbents, and protection of the sorbent from contamination via encapsulation into a porous tubular membrane making MEC a formidable and robust sample preparation technique. After the extraction, a small volume of organic solvent can be used to back-extract the accumulated analyte(s). Due to the high preconcentration factor achieved in the sample preparation using MEC, no solvent evaporation or sample reconstitution is required. The prepared sample can be analyzed using gas chromatography, liquid chromatography, or capillary electrochromatography to obtain complementary information if a suitable solvent compatible with these chromatographic techniques is chosen.

Analytical data obtained from a number of real-life applications of MEC will also be presented showcasing its advantages, extraction characteristics, performance superiority, and analytical figures of merit.

B198 Use of Time-of-Flight Secondary Ion Mass Spectrometry (TOF/SIMS) for Age Dating of Fingerprints and Spatially Resolved Quantification of Illicit Drugs on Fingerprints

Shin Muramoto, PhD, 100 Bureau Drive, Mail Stop 8371, Gaithersburg, MD 20899; Arian C. van Asten, PhD, Netherlands Forensic Institute, Laan van Ypenburg 6, The Hague, Zuid Holland 2497GB, NETHERLANDS; and Edward Sisco, MS, NIST, 100 Bureau Drive, MS 6431, Gaithersburg, MD 20899*

WITHDRAWN

B199 Characterization of Performance-Enhancing Peptides Via Ambient Ionization Time-of-Flight/Mass Spectrometry (TOF/MS)

Kyle E. Vircks, MS, Harris County Institute of Forensic Sciences, 1885 Old Spanish Trail, Houston, TX 77054; Jesse M. Zavala, MS, Harris County Institute of Forensic Sciences, 1885 Old Spanish Trail, Houston, TX 77054; Robert B. Cody, PhD, JEOL USA, Inc, 11 Dearborn Road, Peabody, MA 01960; Warren C. Samms, PhD, 1885 Old Spanish Trail, Houston, TX 77054; and Roger Kahn, PhD, Harris County Institute of Forensic Science, 1885 Old Spanish Trail, Houston, TX 77054*

After attending this presentation, attendees will better understand how preliminary identification of proteins and other large biomolecules can be easily and readily attained using a high-resolution ambient ionization mass spectrometer, instrumentation that is becoming more common in forensic laboratories.

This presentation will impact the forensic science community by demonstrating methods for the analysis of various macromolecules in drug identification laboratories without the need for the specialized protein-sequencing systems typically required.

The increasing presence of recombinant Human Growth Hormone (rHGH) and related performance-enhancing peptides has been observed as internet vendors sell these substances not only to professional competitors but also to the general public. Most drug identification laboratories do not have protocols useful for the analysis and identification of such large molecules. The primary technique of Gas Chromatography/Mass Spectrometry (GC/MS) is limited to relatively small molecules that are readily vaporized at the inlet. This study investigated the feasibility of analyzing macromolecules by using a high-resolution TOF/MS coupled with an ambient ionization source.

Several methods for ionizing proteins prior to entry into the MS were investigated. Electrospray Ionization (ESI), which is common for ionization of such species, as well as Paper Spray Ionization (PSI) and, for simplicity, simple inlet ionization were tested. Mass determinations of various high molecular-weight peptides were successfully attained with all three ionization methods.

Proteins less than 10kDa were amenable to inlet ionization. This involves introducing a small aliquot of dissolved protein directly into the inlet of the MS with a glass capillary. Multiple charge states of the ionized protein were observed, similar to ESI, even in the absence of an externally applied voltage. The mass of the intact protein was calculated by deconvolution of the spectrum either manually or with spectral analysis software. The simplicity of this ionization method makes it especially well-suited for the analysis of small peptides in a typical forensic setting. In contrast, PSI involves spotting small aliquots of dissolved proteins on a triangular piece of filter paper. The tip of the filter paper is then positioned near the MS inlet while high voltage from the onboard voltage supply of the MS is applied to the opposite edge of the paper. Results of inlet ionization, PSI, and ESI approaches will be discussed.

To make it possible for large biomolecules to be further characterized beyond a parent mass, enzymatic digestion of larger peptides is also being investigated.

This project was supported by an award from the National Institute of Justice, Office of Justice Programs, United States Department of Justice. The opinions, findings, and conclusions or recommendations expressed in this exhibition are those of the authors and do not necessarily reflect those of the Department of Justice.

Peptides, Mass Spectrometry, Ambient Ionization

B200 The Effect of Skin Debris on Gunshot Residue (GSR) Detection

Bryan R. Burnett, MS, Meixa Tech, PO Box 844, Cardiff, CA 92007-0844*

After attending this presentation, attendees will understand that skin debris (keratinized epithelial cells derived from the normal process of desquamation by the skin and skin oil) interferes with detection of backscatter electrons in the Scanning Electron Microscope (SEM) from particles on adhesive samplers.

This presentation will impact the forensic science community by showing GSR particles in an SEM analysis of adhesive hand samplers are missed due to overlying skin debris attenuating or blocking backscatter electrons.

GSR particles as large as ten microns are hidden by skin debris when viewed in the SEM by backscatter imaging with an acceleration voltage of 20kV or 30kV. A bleach solution made of sodium and calcium hypochlorite is used to effectively remove the skin debris revealing GSR particles on the adhesive sampler surface. The GSR particles are unaffected by this treatment.

There are two mechanisms for particle adherence on an adhesive SEM sampler. *Primary transfer* of skin debris and particles occurs while the adhesive surface of the sampler remains sticky. This has been noted to be approximately 30 dabs. *Additive transfer*, where particles accumulate on epithelial surfaces, starts with the second dab and increases with additional dabs. With more than 30 dabs, additive transfer predominates as a means for particle transfer from skin. GSR particles adhering to skin debris are removed from the samplers by the bleach treatment; however, there appears to be little risk of removal of the adhesive-entrained particles from the sampler surface by the bleach solution. The bleach treatment described here should only be used after analysis of an untreated sampler due to loss of particles that are adherent on epithelial cell surfaces.

It is apparent an automated SEM analysis at an acceleration voltage at 30kV of a GSR sampler will reveal more particles than at 20kV; however, particles still may be undetectable (below backscatter electron detection threshold) at 30kV due to the attenuation of backscatter electrons by overlying organic material. The bleach removal of the organics on a GSR sampler will reveal previously undetected particles, regardless of the acceleration voltage.

Hidden GSR may be present for a negative-result sampler due to covering by skin debris. It will take reports of actual case analyses (two analyses: before and after bleach treatment) to ascertain whether it is worthwhile to routinely perform the bleach treatment prior to an initial analysis.

Perhaps in that high-profile case, in which the initial analysis is not significant for GSR, an additional analysis with bleach-treated samplers will change that result.

Gunshot Residue, Skin Debris, Backscatter Electron Imaging

B201 Modeling of Elemental and Isotopic Data for Reference Populations Distribution Functions to Be Used in Comparison Evidence and Provenance Intelligence

Jurian A. Hoogewerff, PhD, National Centre for Forensic Studies, Faculty ESTeM, University of Canberra, Bruce - Canberra, ACT ACT 2601, AUSTRALIA*

After attending this presentation, attendees will appreciate the potential of using multivariate geochemical elemental and isotope data to establish background population data for comparison analyses of soil and other natural materials and the use of the spatial distribution of this data for geographical provenancing intelligence.

This presentation will impact the forensic science community by creating awareness that it is possible to produce fit-for-purpose population distribution functions for natural materials with existing geospatial data, which can be used in forensic comparison analysis and for provenance intelligence.

In many instances, comparison analysis of trace evidence involves statistically open sample sets (e.g., that the source of a questioned sample might either be in a control set or not). The extreme case is where no control samples are available. In such a case, any intelligence about a possible source of a questioned sample, or exclusion of non-relevant sources, would greatly assist an ongoing investigation as it could provide guidance as to where to deploy resources.

At first glance, using multivariate elemental and isotopic data, typically 30+ variables, would seem to enable high levels of evidentiary discrimination; however, due to the nature of physical and geochemical processes involved, many of the elemental and isotopic data distributions are not independent and thus typical Random Match Probabilities (RMP) are in the order of 1 in 1,000 to 1 in 100,000, which is much lower than in forensic nuclear DNA analysis where sets of typically 16 independent genetic markers give RMPs in the order of 1 in billions.

As with forensic DNA analysis, it is essential for any forensic or intelligence interpretation to make reasonable assumptions about the structure of the background population distribution (e.g., the Population Distribution Function (PDF)) for each of the variables, element concentration, or isotope ratio, in the relevant context of a case.

With closed sample sets, one can determine the PDFs by measurement, if affordable, and create a closed database. The database can subsequently be used in either a frequentist or Bayesian approach to determine the RMP and/or Likelihood Ratio (LR).

With open sample sets, the challenge is to extrapolate outside a (by its nature) closed measured control database or, as mentioned above, make predictions even without a control database. Although at first instance it may seem paradoxical to predict outside the "box," it is possible to take advantage of the aforementioned systematic physical and chemical processes and natural boundary conditions to model and predict the PDFs of element abundances and isotope ratios in natural materials. The models will have uncertainties but, as they can be quantified, their effect on the RMP and/or LR can be expressed. Typically those uncertainties are small relative to the magnitude of the RMP and/or LR and thus do not affect their probative value.

In this presentation, a combination of climate and geological data models for Europe will be used to create intelligence about the likely provenance of a murder victim from a cold case in the United Kingdom. This cold case is from the south of the United Kingdom where a beheaded and "behanded" torso was discovered in 1991 and buried as unidentified in 1994. Exhumation in 2010 and subsequent oxygen, strontium, and lead isotopic analysis combined with spatial models for these three isotopes gave the cold case investigators the information to reinitiate the search for the origin of the victim.

Distribution Functions, Provenance, Comparisons

B202 Forensic Pathology as a Forensic Science: What Is "Bias" and Why Does It Matter?

Andrew M. Baker, MD, Hennepin County ME, 530 Chicago Avenue, Minneapolis, MN 55415*

After attending this presentation, attendees will understand how forensic pathology — a medical discipline — differs from other forensic specialties and why "history" and "cognitive bias" are not the same thing. The scope of the forensic pathologist's obligations, which go far beyond simply performing autopsies, requires information from many sources to ensure that decedent identification, cause of death, and manner of death are correct. The breadth of this information, which forms the medical history, is sometimes confused with cognitive bias by those outside the medical profession.

This presentation will impact the forensic science community by providing forensic scientists, attorneys, and cognitive scientists with deeper insight into the practice of forensic pathology, giving them a working knowledge of the concepts of cause and manner of death and the methods by which these conclusions are derived. Forensic scientists will be much better positioned to understand, explain, and defend the practice of forensic pathology.

In 2009, the National Academy of Sciences (NAS) Report, Strengthening Forensic Science in the United States – A Path Forward was published. Though largely focused on broad issues spanning many disciplines, it is telling that the NAS assigned medicolegal death investigation its own chapter, not only identifying the challenges unique to this community but also recognizing that the mission of medicolegal death investigation is considerably different than the mission of other forensic disciplines. Many of the deficiencies and needs of the United States death investigation system cited in the report came as little surprise to the death investigation community, as they had appeared in previous reports spanning decades.

Among the forensic disciplines, forensic pathology is (almost) unique because it is the practice of medicine. Its methods are unlike those in other forensic specialties, its goals are different, its scope is often considerably broader, and the types of errors that may occur are unlike those in other forensic disciplines. In all cases falling under medicolegal jurisdiction, the medical examiner is responsible for ensuring the proper identification of the decedent, correctly diagnosing the cause of death, and properly opining on the manner of death. Though these tasks must be done correctly in every instance, the systems in which forensic pathologists perform their duties can run the gamut from ill-equipped offices that are little different from a 19th-century coroner to nationally accredited regional or statewide facilities employing board-certified forensic pathologists and state-of-the-art imaging and laboratory equipment.

In practicing their craft, forensic pathologists support many interests beyond the criminal justice system. Indeed, more than 90% of the sudden, unexpected, or suspicious deaths autopsied and certified by forensic pathologists are — at the end of a thorough investigation — found not to be criminal cases. Proper diagnoses and conclusions in these non-criminal cases provide closure for families, serve as powerful drivers for the allocation of public health resources and research dollars, and prevent the needless prosecution of crimes that never occurred.

Some in the jurisprudence and cognitive science communities have raised the specter of cognitive bias in forensic pathology. There is no *a priori* reason that forensic pathologists should be any more or less immune to cognitive biases than any profession. But forensic pathology's critics sometimes fail to recognize that legitimate medical and contextual history — the foundational basis of the practice of medicine — is not tantamount to inappropriate cognitive bias. Further compounding this misunderstanding is the occasional failure to separate the neutral term "cognitive bias" from pejorative accusations of incompetence, dishonesty, fraud, or corruption.

Manner of death — the medical examiner's classification as to the circumstances under which the decedent died and highly dependent on a variety of contextual data — is a vital component of death certification and has been a key metric for public health in the United States for more than 100 years. Other uses of the manner of death — in particular, in the courtroom — sometimes pose problems.

The optimal way to ensure quality work and defensible conclusions in forensic pathology, and to minimize bias, is to safeguard the independence of medical examiners through legislative or judicial guarantees. Medical examiners must be independent of law enforcement and prosecutors and available to consult with all parties in the criminal justice system.

Pathology, Bias, History

B203 Analyzing Linear Sequential Unmasking

Roger G. Koppl, PhD, Syracuse University, Dept of Finance, 721 University Avenue, Syracuse, NY 13244*

After attending this presentation, attendees will know how to apply decision theory to the evaluation of linear sequential unmasking.

This presentation will impact the forensic science community by demonstrating that linear sequential unmasking may go wrong if the crime laboratory is not an error-tolerant, high-reliability organization.

Linear Sequential Unmasking (LSU) has been proposed as a refinement of sequential unmasking to better limit bias and error in forensic science.[1,2] In the preliminary stages of analysis, examiners would be required to associate a degree of confidence with each determination made as their analyses unfold in real time. These confidence attributions are strategic choice variables for forensic examiners. The value of LSU is highly dependent on the organizational context, which influences the costs and benefits of different examiner choices. Confidence attributions may be informative or meaningless depending on the "error tolerance regime" created by the overall organizational context of the crime laboratory. High-reliability organizations accept that errors will happen and thus attempt to control the consequences of error through measures such as redundancy rather than responding to individual errors with blame and opprobrium.[3] As Rouse and Morris have put it, "Errors are not inherently unacceptable; however, it may be that the consequences of error are unacceptable. From this perspective, one may be able to tolerate errors as long as consequences can be controlled."[4] Linear sequential unmasking will not improve forensic science unless crime laboratories become error-tolerant, high-reliability organizations.

These results of decision theory throw into question linear sequential, which is a recent important proposal to combat observer effects and bias in forensic science. If the proposal is to have its intended effect of improving forensic science, it must be preceded by measures to improve error tolerance within forensic science. Thus, some of the emphasis and attention should be shifted from individual error and the cognition of individual forensic scientists and toward the organizational context in which they work. LSU will improve forensic science only if that context is improved. In particular, it will improve forensic science only if crime laboratories are error tolerant. The future of forensic science depends significantly on whether the forensic science community recognizes both the importance of the error tolerance regime within which individual forensic scientists work and the role of organization in shaping the error tolerance regime.

Linear Sequential Unmasking, Bias, Error Tolerance

B204 Three Roads Converge: The Formation of the Houston Forensic Science Center

Daniel D. Garner, PhD, Houston Forensic Science Center, 1200 Travis Street, 20th Fl, Houston, TX 77002; Michael Grojean, PhD, Houston Forensic Science Center, 1200 Travis Street, Houston, TX 77002; and Amy L. Popejoy, MS, Houston Forensic Science Center, 1200 Travis Street, Ste 2552, Houston, TX 77002*

The goal of this presentation is to share best practices and lessons learned with other forensic science centers as they consider the pursuit of independence. This presentation's conclusions will also assist more traditionally structured forensic science centers as they adapt to shifting requirements, changing legislation, and an increasing demand for objectivity, quality, and timeliness of services.

This presentation will impact the forensic science community by illustrating the roles that culture, communication, leadership, and employee engagement play in the formation of a new forensic entity. Attendees will be able to replicate this approach for their own organizations to more effectively manage their changes.

The Houston Forensic Science Center (HFSC) was established in 2012 as a Texas local government corporation whose purpose is to provide the City of Houston and the surrounding region with independent forensic services. In 2014, HFSC took over control and management of the Houston Police Department's (HPD) Crime Lab, Crime Scene Unit, and parts of the Identification Division. This is the first significant transition in the United States in which a traditional extension of law enforcement reorganizes into an independent forensic body committed to sound business practice, scientific rigor, and strong performance orientation.

Subsequently, this also created a unique set of circumstances which generated substantial risk for failure. In practice, three of the riskiest activities are mergers/acquisitions, large organizational change, and significant culture shift. HFSC's formation contained elements of all three. Three separate systems converged: HPD classified officers, City of Houston (COH) civilian employees, and HFSC's newly hired employees. Personnel from the two established systems (HPD and COH) had strong cultures, long institutional memory, and a degree of uncertainty, sometimes even skepticism, about the new company. HFSC employees were new arrivals, largely joining after the company's formation and entering the ranks alongside HPD and COH workers. The three groups have differing benefit packages, labor contracts, promotion channels, performance systems, and management structures.

This presentation is offered as a case study on how to mitigate the risk of this type of organizational change, while using the diverse backgrounds and differing cultures to build strength and capability. Engaged management, open and ongoing communications, a workforce involved in the change, and a thorough examination of the culture needed for success had the greatest impacts on the process.

Organizational research suggests engaged management is critical to mitigate the risk of major change and culture shift. HFSC's board of directors is a balanced governing body that ensures the Center's objectivity and independence. The internal management and leadership team reflects the diversity of the company's three separate "feeder systems." Finally, HFSC's organizational structure is designed around eight forensic disciplines: firearms, controlled substances, biology, latent prints, digital, audio/video, toxicology, and crime scene, each with strong leadership.

For the new venture to succeed, both the legacy workforces and the new hires have to buy into the required organizational change and culture shift. The cornerstone is a shared vision to serve the justice system through independent, objective science, coupled with active and open communications. This included frequent company meetings to distribute information and solicit feedback, strong intra-discipline communication and a single-platform Information Technologies (IT) system. Further, staff were instrumental in the change process, participating in committees focused on planning, quality, and human resources.

Ultimately, all change must be firmly rooted in culture to have long-term viability and sustainability. Tools to measure the necessary culture for HFSC's success were developed to monitor, adjust, and shape the change and progress. This includes key cultural dimensions mapped onto "as-is" and "should-be" frameworks. Both qualitative and quantitative data were collected through focus groups, individual interviews, observational assessment (including crime scene ride-alongs), and surveys. Initial qualitative analysis identified keywords, concepts, and themes resulting in six broad values and 25 markers. The six values are professionalism, business focus, teamwork, agility, stewardship, and ethics. Subsequent quantitative collection and analysis allowed for the comparison of the culture that currently exists within HFSC and its ideal culture. These results then form the basis for allocation of attention, resources, and effort to areas that will have the greatest impact on culture shift.

Incorporation, Independence, Culture

B205 Embracing Change: The Challenges and Rewards of Transitioning From the Bench to Management

Julia A. Dolan, MS, Bureau of ATF, Forensic Science Laboratory, 6000 Ammendale Road, Ammendale, MD 20705*

After attending this presentation, attendees will better understand the challenges facing managers in forensic science laboratories and the differences in knowledge, skills, and abilities required by managers versus those needed by scientists. This presentation will also offer some recommendations to prepare for this type of career change and to improve the transition process.

This presentation will impact the forensic science community by providing a realistic view of the challenges faced by managers in forensic science and will provide an approach for laboratory systems to proactively address potential knowledge and skills gaps for their employees new to management and for those considering such a transition.

Most forensic science laboratories select their first-line supervisors and laboratory directors from personnel who have worked in their system — people who are good forensic scientists. One challenge with this model is that most bench scientists, having studied forensic science, chemistry, biology, etc., haven't had formal training in business, leadership, conflict resolution, or management. Although technical knowledge, skills, and abilities are an important foundation for forensic science laboratory leadership, these talents only represent a fraction of what is necessary to be an effective leader. Forensic science laboratory managers must also have the ability to communicate effectively in order to share workplace objectives and address personnel issues with subordinates as well as the ability to influence superiors in the organization regarding needs such as training, equipment, and personnel resources. Knowledge of the procurement process, how to effectively develop and defend budgets, how to motivate employees and address performance problems as well as myriad human resources and legal issues are all critically important for supervisors at all levels. Unfortunately, many forensic scientists are not provided opportunities to develop these skills prior to being considered for management positions. Of even greater concern, some new supervisors are not provided adequate support and training even after obtaining a managerial position.

Many of these challenges may be further exacerbated when a former peer is promoted from within to a supervisory position. Personnel issues can be more difficult to handle when a former peer is involved and the nature of pre-existing relationships have changed. Dealing with conflict resolution, performance evaluations, or poor performance can be problematic for seasoned leaders and even more so for new supervisors that were recently part of the peer group.

Other challenges include the constant need to do more with less and the increasing public scrutiny of forensic science. Infrequent, but highly publicized, cases of inadequate science or malfeasance on the part of forensic scientists have put all of forensic science in a defensive posture. This presentation will focus on some of the unexpected issues that a technical manager may encounter and how to prepare for them. It will also highlight some of the hidden benefits of providing leadership in today's forensic science laboratory.

Forensic Science, Management, Career

B206 Using Results-Based Data to Make Informed Management Decisions

Jenna L. Oakes-Smith, MFS, St. Louis Metro Police Department, 1915 Olive Street, St. Louis, MO 63103*

After attending this presentation, attendees will have a better understanding of how to make use of analytical result data to create and improve laboratory policies and management decisions. The data generated by a metropolitan police laboratory will be presented as a case study.

This presentation will impact the forensic science community by demonstrating how empirical-quality data can be used to focus and support management decisions. Using data that evaluates the quality of the evidence being submitted, managers can direct resources to evidence that will most likely yield usable results. Managers may also evaluate the effectiveness of their staff by using both quality and quantity metrics.

As the media continues to highlight the impact that forensic analyses can have on cases, the public and the courts are demanding more and more testing to be performed on evidence; however, as these requests increase, the resources needed to support them do not. Forensic laboratories are simply told to do more with less and to cut their backlogs at the same time that evidence submission is increasing. Intuitively, the logical choice would be to not process certain types of evidence routinely, but who makes those decisions and how can they be justified?

A laboratory must decide which types of evidence and which procedures yield the best results. This decision should not be based purely on analyst or management intuition, but rather on empirical, statistical data. By recording the results associated with particular evidence types, laboratories can decide how to prioritize evidence samples. Further, the same data can be used to evaluate the quality of work of an analyst. Are there trends in the data that shows that an employee consistently takes swabs that yield more useable DNA? Does one analyst have better results with differential extractions than another? Is there a crime scene technician that has a higher-than-average percentage of latent lifts with no value? By examining the data, laboratories can direct resources to training individuals to ensure that the evidence is collected and processed with the best available techniques. By focusing on the best evidence processed with the most effective methods, laboratories can ensure that they will get the most bang for their buck.

This presentation will provide the results of the St. Louis Metropolitan Police Department Crime Lab's DNA and latent sections as a case study for this data-driven management methodology. The laboratory began using their Laboratory Information Management System (LIMS) system two years ago to evaluate the quality of their analytical results. The results, as well as the related policy questions, will be presented.

LIMS, Management, Quality

B207 Applying the Queuing Theory in Forensic Cases Management

Khudooma S. Al Na'imi, MSc, Abu Dhabi Police General Directorate, Forensic Bio Sect, Forensic Evidence, PO Box 66722, Al Ain City - Abu Dhabi , UNITED ARAB EMIRATES*

After attending this presentation, attendees will understand some principles of the queuing theory.

This presentation will impact the forensic science community by introducing a key aspect of the queuing theory, which can be a means of more efficient forensic case management. This may accelerate the operation of a forensic laboratory and help take advantage of the available resources in a suitable manner, taking into consideration that there is less attention to the use of administrative principles in forensic sciences in general.

Processing more forensic cases is one of the challenging points in many forensic laboratories. This can result in performance and capacity reduction, formation of backlog, and unsatisfied customers (prosecutors, victims, the accused, and the courts). To be able to handle more forensic cases in an efficient manner, management queuing theory can be applied in different stages of the cases. There are many waiting intervals in forensic cases, such as before receiving, waiting in lab reception, in different laboratory processes, and so forth.

In queuing theory, "λ" is the Arrival Rate and "μ" is the Service Rate . The average number of cases (or evidence waiting to be examined) is $L=\lambda 2/\mu(\mu-\lambda)$. The average time cases or evidence spends waiting to be examined is $Wq=\lambda/\mu(\mu-\lambda)$. The probability that the laboratory is busy getting new cases or evidence is $\rho=\lambda/\mu$.

There are several queuing models according to the organizational situation such as: M/D/1 case (mean random arrival of customers, deterministic service, and one service channel-one examination); M/M/1 case (mean random arrival, random service, and one service channel); M/M/C case (mean random arrival, random service, and C service channel); and M/M/C/K case (random arrival, random service, and C service channels and K maximum number of vehicles in the system).

In this research, approximately 50 forensic biology cases were reviewed. The average number of customers or evidence waiting for service, the average time a case spent in queue, and the probability of services being busy was calculated using the above equations. The information and results were used to improve the work of the laboratory, better communicate with customers, and reduce the queuing time for cases. There is a need for further attention from the forensic community to the queuing theory in managing forensic cases, especially in a period of increasing services requests.

Queuing Theory, Case Arrival, Forensic Services

B208 Quality Assurance of the Biostatistical Workflow in Forensic Genetic Casework

Andreas Tillmar, PhD, National Board of Forensic Medicine, Artillerigatan 12, Linkoping SE-58758, SWEDEN; and Gunilla Holmlund, PhD, Rättsmedicinalverket, Artillerigatan 12, 58758, Linköping, AL 58758, SWEDEN*

After attending this presentation, attendees will understand the different components of a biostatistical workflow in forensic genetic casework. Attendees will also gain insight into different aspects of the quality assurance of such a workflow as well as become aware of the challenges in the validation process and the maintenance of personnel competence.

This presentation will impact the forensic science community by contributing to ideas for the design and quality assurance of a complete biostatistical workflow to be used in forensic genetic casework. This presentation will also illustrate how validation of this workflow can be carried out within an accredited laboratory.

Quality assurance is a key element in an accredited forensic laboratory. Quality involves several components such as: (1) validation of methods, instruments, and software; (2) documented maintenance; (3) secured chain of custody; (4) documented operating procedures; (5) traceability; and, (6) proven competence of the staff. The general goal is to produce test reports of forensic investigations with legal certainty.

DNA is a powerful tool in forensic analysis for linking a suspect to a crime scene, resolving biological relationships, and identifying disaster victims. Traditionally, DNA investigations can be divided into two parts: (1) the establishment of DNA profiles; and, (2) the evaluation of the evidential weight of these DNA profiles, given some hypotheses about the true circumstances. There are well-documented standards for quality assurance of the first part (for example, DNA extraction and DNA typing methods), but for the second part, guidelines have not yet been established within the community.

The evaluation of the weight of evidence, using a biostatistical workflow, includes several components such as different computational methods, reference data, secured transfer of case data, and expert opinions made by reporting officers.

Sophisticated biostatistical computation models are implemented in dedicated software packages making up the basis of the biostatistical workflow. To assure the quality of this workflow requires not only validation of software packages per se, but also validation of population reference databases and reference parameter settings. It also requires thresholds to be set for different verbal conclusions that are used in the final report, and it embraces qualification demands for the authorization of competence of expert practitioners. It also includes proficiency testing of the workflow as a whole.

A biostatistical workflow for use in forensic genetic casework has been designed, validated, and implemented. The workflow contains four different software packages and population reference data for more than 50 autosomal, X-chromosomal, and Y-chromosomal DNA markers from three different populations. Competence requirements specific for each software and type of casework have been implemented. The requirements also include maintenance of competence through annual exercises. In addition, parameters for validation of any changes in the workflow, such as a new version of a software, have been established to maintain continuity.

Quality Assurance, Statistics, Forensic Genetics

B209 Success Rates From Touch DNA in Property Crimes

Tammy Taylor, MS, Harris County Institute of Forensic Sciences, 9000 Almeda Road, #7304, Houston, TX 77054; Michael A. Donley, MS, 1885 Old Spanish Trail, Houston, TX 77054; Diana Gonzalez, MS, 1885 Old Spanish Trail, Houston, TX 77054; Nikia S. Redmond, MSFS, 1885 Old Spanish Trail, Houston, TX 77054; Katherine Welch, MSFS, Harris County IFS, 1885 Old Spanish Trail, Houston, TX 77054; and Roger Kahn, PhD, Harris County Institute of Forensic Science, 1885 Old Spanish Trail, Houston, TX 77054*

After attending this presentation, attendees will be aware of the rate of success for obtaining useful DNA from touch DNA in property crimes.

This presentation will impact the forensic science community by providing data on touch DNA success rates from a laboratory with no limitations on case acceptance.

Genetic evidence left by a perpetrator at a property crime in the form of epithelial cells is often described as touch DNA. Touch DNA samples include any object that the perpetrator may have touched at the crime scene or any personal item left behind. These items include objects handled at the crime scene, tools used during the crime (e.g., flashlight or screwdriver) and clothing worn by the suspect. Items worn by the perpetrator have much higher levels of genetic material compared to other items that were briefly touched. The Harris County Institute of Forensic Sciences (HCIFS) Forensic Genetics Laboratory accepted all touch DNA evidence from property crimes from 2009 to 2015 without limit (i.e., no case acceptance policy was in place). The DNA results for touch and touch clothing DNA evidence from property crimes from 2009 to 2013 were categorized and analyzed to determine success rates as far as profile Combined DNA Index System (CODIS) eligibility and CODIS hits.

In total, the laboratory analyzed 4,548 property crime cases containing clothing and touch samples. Of these cases, 672 had clothing items left behind that were examined for the presence of DNA from the wearer of the item. Of these 672 cases, 435 (65%) produced a DNA profile suitable for entry into CODIS. Of the 4,548 cases, 3,876 cases had evidence touched by a suspect with 703 (18%) suitable for CODIS entry. The CODIS hit rate for both categories was similar with 53% (231 of 435) of clothing cases and 44% (309 of 703) of touch cases with CODIS hits. The offender hit rate in both categories was also similar at ~80%. Overall, 34% of the cases with clothing samples and 8% of the touch cases had some type of CODIS hit.

Despite the modest 8% hit rate, the number of touch cases submitted per year to the HCIFS Forensic Genetics Laboratory increased more than three-fold from 2009 (402) to 2013 (1,348) and, when polled, submitting law enforcement agencies strongly supported the continuation of touch DNA testing as the best opportunity to link cases and to identify possible perpetrators for burglaries and thefts.

Touch DNA, Property Crimes, CODIS

B210 Forensic Genetics in Brazil: A (Still) Brief History

Ana Paula S. Doval, Federal Police Department, Inc, Sais Quadra 07 Lote 23 - Sps, Brasília, Federal District 70610-200, BRAZIL; Meiga A.M. Menezes, MSc, Federal Police- Brazil, Sqsw 303 Bl B Apt 108- Sudoeste, Brasilia, Distrito Federal 70673302, BRAZIL; Guilherme Silveira Jacques, MSc, SAIS 07, Lote 23, Brasilia 70610-200, BRAZIL; and Helio Buchmuller, PhD*, SMPW 21, cj 2, lt 8, cs C, Brasilia, Distrito Federal, BRAZIL*

After attending this presentation, attendees will better understand how forensic genetics has been growing in Brazil and how this tool could help in reducing the threatening rate of 53,646 homicides and 50,320 rapes, estimated in 2013.[1]

This presentation will impact the forensic science community by presenting the history of forensic genetics in Brazil.

The history of forensic genetics began in 1986 in England. Since then, DNA testing has become optimized and standardized for its use as criminal evidence by the international community. Two years later, a paternity test using DNA was performed in Brazil by Sérgio Pena, in a non-official laboratory. Despite Pena's success, the first official DNA laboratory was not created in Brazil until 1994 at the Police of Federal District (Brasília).

In 2004, when only five of the 27 Brazilian states had official forensic DNA laboratories, the Ministry of Justice implemented a national policy committed to providing infrastructure, well-trained forensic scientists, and integration between states and the Federal Police (PF). The laboratory web then began to be woven. The next year, PF's DNA laboratory was set up and started promoting competency events for official forensic scientists from all over the country. The laboratory team made their first contact with Federal Bureau of Investigation (FBI) in the same year, intending to acquire the Combined DNA Index System (CODIS). They had also planned for the implementation of a quality system since the laboratory's inauguration. This was achieved through an **International Organization for Standardization (**ISO) 17025 consultation in 2008 and accreditation in 2014. Legal initiatives for a database creation and for legal writ of biological sample collection from sentenced criminals were also undertaken.

In 2009, an agreement was made between the FBI and Brazilian PF, allowing the use of CODIS (5.7.4 and 6.1 versions) in official laboratories. The 6.1 version was used for the second time in the world and the first time in a plane crash to support victim identification from the Air France 447 disaster. Experts from Brazilian PF identified all of the 50 bodies that were found using DNA, conforming to the International Criminal Police Organization (INTERPOL) proceedings, based on 430 reference profiles from relatives and direct references.[2] After the CODIS assignment, Brazilian states initiated the formal registration of their own databases. At the same time, national database conditions were provided. In 2012, Brazilian Congress passed a bill to collect DNA from those convicted of hideous crimes as well as from arrestees, under the conditions of a court order.[3] In 2013, a decree put 2012's law into power and provided national database creation, as well as the DNA Databases Network, a web that would link state, federal, and national databases.[4] Another two practical databases have been helping investigations in Brazil: (1) for missing persons from the military dictatorship period; and, (2) a national missing children and teenagers bank.

Forensic sciences are also alive at academic level. The Brazilian Academy of Forensic Sciences (BAFS) was conceived in 2011 during Brazil's candidature in the International Association of Forensic Sciences (IAFS) and was formally founded in 2012. Two conferences have been held since BAFS creation, promoting integration between research and applied knowledge for official laboratories.

In conclusion, this presentation provides a brief summary of forensic genetics development in Brazil and explains how DNA testing has been gaining space and strength at the judicial level.

Brazil, History, DNA Database

B211 From Cold Case to Solved Crime

Lisa Mertz, MS, OCME, Dept of Forensic Biology, 421 E 26th Street, New York, NY 10016; and Krista Currie, MSc*, OCME, Dept of Forensic Biology, 421 E 26th Street, New York, NY 10016*

After attending this presentation, attendees will better understand the complexities and challenges faced in processing cold cases and will be presented with a case file example.

This presentation will impact the forensic science community by bringing to light the challenges faced in processing cold cases as well as the need to continue efforts to solve these open cases.

DNA testing has become the single most important forensic tool available in solving, prosecuting, and preventing crime; however, DNA processing techniques have only become well adopted and routine in aiding criminal investigations within the past 15 to 20 years. This is in part due to new technological advances in the field. With the implementation of new technology, cold cases are able to be re-accessed to see what may be possible in terms of examining evidence for biological fluids and/or biological material.

Investigations into cold cases face the same basic challenges as new investigations in terms of DNA testing, namely obtaining a DNA profile that can be uploaded to the database of forensic unknown samples to be compared to known individuals in order to solve the case. Still, additional complexities for cold cases exist. Cold cases may require testing on items of evidence that were unable to be processed at the time due to a lack of technology or due to obtaining an unsuccessful result. Processing a cold case involves greater cooperation among law enforcement, the crime laboratory personnel, and the district attorney's office. This is due in large part because simply locating the items of evidence to be processed can be both time consuming and challenging. Similarly, locating previous reports and previous DNA testing results can take great effort. From past reports, the crime laboratory can make a determination as to what DNA testing or additional testing is now plausible. After determining what is possible, challenges are faced with the processing of evidence that is old and may only result in the recovery of degraded DNA. Challenges are also faced in dealing with items of evidence that may have been unknowingly contaminated at the scene in a pre-DNA world in which there was less emphasis on proper protective equipment. Also, obtaining DNA elimination samples increases the challenge. A DNA profile may be able to be recovered on the item of evidence tested; however, obtaining elimination samples from witnesses or law enforcement personnel who may have come into contact with the item may be impossible.

Processing cold cases can be challenging not only in terms of the DNA processing, but also in obtaining funding and employing staff to locate, vet, and analyze these difficult items of evidence. Also, one must consider the legal limitations, as the statue of limitations may have already passed for these cases.

As a result of all the above-listed challenges, several cold cases remain unprocessed to this day and thus stay cold. A successful cold case will be presented. The challenges faced in this laboratory will be highlighted as well to showcase the need for the continued processing of these open cases.

Cold Cases, Unsolved, DNA

B212 National Institute of Justice's (NIJ's) "Using DNA Technology to Identify the Missing" Program: An Update

Charles M. Heurich, MFS, National Institute of Justice, Dept of Justice, OJP, 810 7th Street, NW, Rm 7204, Washington, DC 20531*

After attending this presentation, attendees will understand the NIJ's funding for solving missing persons and unidentified human remains cases. Attendees will also receive data on the impact of the program to date.

This presentation will impact the forensic science community by educating the community about an NIJ funding program that their agencies may not be aware of as well as the impact this program has had on solving cases.

The NIJ is the research, development, and evaluation branch of the Department of Justice. NIJ is the federal government's lead agency for forensic science research and development as well as for the administration of programs that facilitate training, improve laboratory efficiency, and reduce backlogs. The mission of the NIJ's Office of Investigative and Forensic Sciences is to improve the quality and practice of forensic science through innovative solutions that support research and development, testing and evaluation, technology, information exchange, and the development of training resources for the criminal justice community. Through the research, development, testing, and evaluation process, the NIJ provides direct support to crime laboratories and law enforcement agencies to increase their capacity to process high-volume cases and provide needed training in new technologies.

Based on a survey published by the Bureau of Justice Statistics in 2007, it is estimated that approximately 4,000 sets of unidentified human remains are found every year, 1,000 of which remain unidentified after one year. In addition, on any given day, there are approximately 100,000 people reported missing. Since 2003, the NIJ has initiated programs dedicated to assisting state and local law enforcement agencies and crime laboratories in solving missing persons cases and identifying human remains. In April 2005 at a national strategy meeting sponsored by the NIJ, former Deputy Attorney General James B. Comey spoke about the lack of uniformity in multiple Federal Bureau of Investigation (FBI) databases. As a result of the meeting, he directed the NIJ and the FBI to establish a national task force to assess existing databases and identify how to better encourage, facilitate, and achieve greater use of these databases. This task force recommended the creation of a new database which became the National Missing and Unidentified Persons System (NamUs).

This presentation will discuss the NIJ's "Using DNA to Identify the Missing" program, its goals and objectives, and show success stories associated with the program. The funding amounts, number of awards, and performance metrics, including number of samples tested, profiles developed, profiles uploaded to the Combined DNA Index System (CODIS), and DNA hits will all be presented. Successful project designs and several cases in which identifications have been made will be discussed. In 2007, the NIJ released NamUs to the public. The system is composed of three individual databases: a missing persons database, an unidentified remains database, and an unclaimed persons database. This presentation will also discuss some brief updates on the NamUs system, including future plans for the system.

Missing Persons, NIJ, DNA

B213 The Testing of Unsubmitted Sexual Assault Kits: An Update on the National Institute of Justice-Federal Bureau of Investigation (NIJ-FBI) Sexual Assault Kit Partnership

Gerald M. LaPorte, MSFS, National Institute of Justice, Office of Inv & Forensic Science, 810 Seventh Street, NW, Washington, DC 20531; and Heather E. Waltke, MS, 3601 Connecticut Avenue, NW, Unit 120, Washington, DC 20008*

After attending this presentation, attendees will have updated knowledge concerning federal support through the NIJ-FBI Sexual Assault Kit Partnership to reduce the number of Sexual Assault Kits (SAKs) waiting to be tested in the nation's law enforcement agencies.

The presentation will impact the forensic science community by conveying information the Partnership has garnered with regard to the collection, processing, and testing of SAK evidence from law enforcement agencies across the country.

The NIJ — the research, development, and evaluation agency of the United States Department of Justice — leads the nation in supporting the forensic sciences through research and by providing state and local crime laboratories with funding to help process and test evidence more efficiently in an effort to reduce backlogs. This presentation will provide an update on the NIJ-FBI Sexual Assault Kit Partnership initiative designed to help inform evidence collection, processing practices, and testing protocols for SAKs.

This research initiative began accepting SAKs from law enforcement agencies in September 2015 and has been helping to address a major need in this nation's forensic science and criminal justice communities to support state and local law enforcement agencies in their efforts to reduce the number of unsubmitted SAKs. The focus of this effort has been in the collection and analysis of valuable data concerning the nature of sexual assault evidence contained in previously unsubmitted SAKs. The effort has begun yielding knowledge related to the various processes associated with the intake of sexual assault evidence into the laboratory as well as with screening, testing, and analysis. An understanding of these processes is fundamental in the effort to inform best practices for collecting, analyzing, and testing evidence from sexual assault cases, particularly when faced with the processing of large quantities of unsubmitted SAKs. The knowledge garnered as a result of this continuing effort will be used to fulfill the long-term goal of improving current and future best practices for collecting quality evidence and processing SAKs in a more timely and efficient manner. This initiative directly supports the goal of carrying out analyses of samples from untested, unsubmitted SAKs so DNA profiles can be developed and placed in the National DNA Index System (NDIS). More violent crimes are solved as more DNA profiles are placed in the NDIS, which is considered one part of the Combined DNA Index System (CODIS), the Federal Bureau of Investigation's (FBI's) program of support for criminal justice DNA databases as well as for the software used to run these databases. The NDIS has been particularly helpful to investigations that are very old and no longer producing new leads. The Partnership has already begun generating CODIS hits throughout the nation, and the upload of hundreds of eligible profiles generated from DNA analysis as a result of this research provides direct aid in the investigation of violent crimes involving sexual assault.

Sexual Assault Kit, DNA Testing, Sexual Assault

B214 What Errors Are We Looking for and How Can We Look for More?

Charlotte J. Word, PhD, PO Box 5207, Gaithersburg, MD 20882*

After attending this presentation, attendees will better understand how different types of errors that may occur in a forensic science laboratory can be discovered and what steps may be taken to expand the detection of additional errors that occur during testing and reporting of test results.

This presentation will impact the forensic science community by providing information on the importance of error detection and the approaches that can be used to expand the recognition of errors, with particular focus on the detection of false positive and false negative results and conclusions.

It is human nature to make mistakes. It should come as no surprise that human errors occur in crime laboratories, and thus all accredited forensic science laboratories must have quality-assurance programs in place with procedures for the detection, evaluation, and resolution of errors. Technical errors, failures in the testing assay, and some types of contamination can often be detected through the use of positive and negative controls. Technical review processes can often prevent the reporting of some mistakes in the final laboratory report, such as misinterpreted data and typographical errors, through the independent re-evaluation of the data, interpretation, and conclusions. Proficiency tests are required for the routine monitoring of the laboratory test assays and for the ability of the analyst to correctly perform the testing procedure and report the test results and conclusions. Based on any findings of errors detected through these various processes, it is common practice for the laboratory staff to research the cause of the errors and to take corrective actions to ensure the appropriate test results are obtained and reported in an affected case. In addition, when the cause of the error can be determined, corrective actions can be put in place to improve policies, procedures, and practices in the laboratory to prevent future errors of a similar nature.

Many of these quality-assurance practices aid in the detection of errors that can be corrected prior to the reporting of the final test results and conclusions. But how effective are these procedures for detecting *all* errors that are made in a laboratory? Are there other practices that could be considered for the detection of additional errors that are now being incorrectly reported? Are there additional mechanisms that can be put in place in a laboratory to improve the recognition of false positive or false negative associations (defined here as the incorrect association of an individual to evidence from a crime scene and the failure to detect the association of an individual to evidence from a crime scene, respectively)? These questions will be the basis of this presentation, which will provide information regarding what errors are currently being looked for, the effectiveness of that self-assessment, and some suggestions of methods that could be employed to expand the evaluation of laboratory error and detection with the goal of providing the best services to the forensic science community.

Errors, Quality Control, False Positive

B215 The Proper Use of Standard Reference Material 2372 (SRM 2372) Human DNA Quantitation Standard for the Calibration of Commercial Quantitative Polymerase Chain Reaction (qPCR) Kit DNA Standards

Erica L. Romsos, MFS, 100 Bureau Drive, MS 8314, Gaithersburg, MD 20899; Margaret C. Kline, MS, 100 Bureau Drive, Gaithersburg, MD 20899; David L. Duewer, PhD, 100 Bureau Drive, Gaithersburg, MD 20899; and Peter M. Vallone, PhD, 100 Bureau Drive, Gaithersburg, MD 20899-8311*

After attending this presentation, attendees will understand why the National Institute of Standards and Technology (NIST) produces SRM 2372 Human DNA Quantitation Standard and how that standard should be used within an individual laboratory to calibrate internal commercial qPCR kit DNA standards.

This presentation will impact the forensic science community by bringing attention to the differences in commercial qPCR kits based on the lot of the DNA standard and the quantitation chemistry employed. The proper use of SRM 2372 will also be presented.

The NIST SRM 2372 Human DNA Quantitation Standard was produced to support the need for a human-specific DNA quantitation standard in forensic casework as a calibrant for commercially produced DNA standards. SRM 2372 is intended primarily for use in the value assignment of human genomic DNA forensic quantitation kit materials. SRM 2372 consists of three materials, one single-source male, one multi-source female, and one multi-source male/female mixture, all solubilized in TE-4 buffer.[1] The application of SRM 2372 is for calibration of commercial qPCR kit standards to aid in proper quantification of unknown DNA samples within a forensic workflow.

Commercial Short Tandem Repeat (STR) assays used by the forensic human identity community require tight control of the amount of sample DNA amplified in the Polymerase Chain Reaction (PCR). This requires the ability to reproducibly measure the concentration of human DNA in a casework sample extract prior to input in the PCR reaction. Approximately 500pg-1,000pg of input DNA will provide a balanced and an interpretable STR profile. Commercially available qPCR kits routinely are relied upon to determine the concentration of casework extract within forensic laboratories; however, assays employed rely upon commercial DNA standards for relative quantitation estimates.

Data shown will demonstrate the need for an SRM for the calibration of commercially produced qPCR DNA standards. This is due to an observed ~50% variation in measured DNA concentration between multiple lots of a commercially available DNA standard. This variation may lead a laboratory to possibly overestimate or underestimate the concentration of an unknown sample that could lead to an incorrect dilution within the PCR workflow. In addition, the variation in assigned concentration across several qPCR chemistries will be shown. The use of SRM 2372 is intended to enable the comparison of DNA concentration measurements over time, production lots, and within an individual laboratory. Additionally, manufacturers can use SRM 2372 to validate the values assigned to their own commercial qPCR kit DNA standards. Individual forensic laboratories should use SRM 2372 to validate the concentration of DNA qPCR quantitation kit standards and to verify the assigned concentration of an in-house or commercial DNA standard prior to use. This recalibration will result in decreased variability between varying lots of qPCR kit DNA standards. A specific example of how to properly use SRM 2372 to recalibrate a commercial qPCR kit DNA standard will be presented.

SRM 2372, qPCR, Standard

B216 Is the Factor of 10 Still Applicable Today?

Simone Gittelson, PhD, National Institute of Standards and Technology, 100 Bureau Drive, MS8980, Gaithersburg, MD 20899-8980; and John S. Buckleton, PhD, PB 92021, Auckland , NEW ZEALAND*

After attending this presentation, attendees will have an updated empirical measure of the variability inherent in the assignment of a match probability.

This presentation will impact the forensic science community by showing results for the variation of match probabilities obtained using different allele frequency database data from the same ethnic group. The results from this study indicate that this variation can be larger than a factor of 10 when comparing match probabilities obtained for different populations from around the world.

The assignment of the weight of DNA evidence depends on a number of factors (allele probability estimates, the population genetic model used, the value of the coancestry coefficient, etc.). One of these factors is the allele probability estimates from a database. Key considerations include, but are not restricted to, representativeness and size of the database. The appropriateness of any particular database to any given case is a matter of judgment. This judgment is often based on relevant background information such as the location of the crime. It involves an unavoidable subjective element.

In 1996, the National Research Council (NRC) Committee on DNA report stated that, ‘‘…empirical studies show that the differences between the frequencies of the individual profiles estimated by the product rule from adequate subpopulation databases (…) are within a factor of about 10 of each other...’’.[1] This statement has proven valuable as a gauge on variability caused by the database; however, it was developed at a time before Short Tandem Repeat (STR) multiplexes and is overdue for an update.

The present study examines the validity of the “factor of 10” method for the interpretation of DNA typing results today. It compares the match probabilities obtained using hundreds of different allele frequency databases from around the world. More specifically, this study first simulated sets of genotypes from a database of interest based on the allele frequencies of that database. Then, match probabilities were obtained using the allele frequency data from the original allele frequency database used for simulating the set of genotypes. Similarly, match probabilities were obtained using allele frequency data from each of the other databases in the study corresponding to the same ethnic group. The match probabilities obtained using the data from the other allele frequency databases were then compared with the match probabilities obtained using the original allele frequency database used for simulating the set of genotypes. The results of these comparisons indicate variation among the match probabilities that is greater than a factor of 10.

DNA Interpretation, Allele Probabilities, Subpopulations

DIGITAL & MULTIMEDIA SCIENCES

C1 Differential Forensic Analysis of Periodic Mobile Forensics Images

Mark D. Guido, MS, The MITRE Corporation, 7515 Colshire Drive, Mclean, VA 22102*

After attending this presentation, attendees will better understand applying comparison forensic images from mobile devices before, during, and after an event/mission for rapid and targeted triage.

This presentation will impact the forensic science community by demonstrating the research and results of an automated mobile forensic image comparison capability.

Differential analysis of forensic images or, in other words, the direct comparison of forensic images before, during, and after an event of interest allows forensic examiners the ability of avoiding analyzing a large amount of information that hasn't changed and instead focus on the data that has changed between images.[1] This has the effect of greatly speeding up analysis and intelligence gathering.

Periodic Mobile Forensics (PMF) is a research project that automates differential analysis to address some new-use cases: (1) mission hotwash — users control the starting point of the device, and compare the device at the end of the mission to gather data, identify usage, and assess whether the device was targeted or compromised during the mission; and, (2) travel to areas of concern — the device is used during travel to potentially hostile areas, when users want to assess whether it was targeted or compromised.

There are a few unique capabilities in PMF's approach to differential analysis. First, in the above used cases, PMF needs only to temporarily modify the device (sometimes even only after mission usage) and can reset the device back to the stock image, with no on-device software indicative of any modifications. Second, PMF is an automated differential analysis system, not based upon changes to files, but rather by blocks (bit runs) of data. PMF hashes the entire Negative And (NAND) storage by offset and only needs to collect the data that has changed on the device during the event of interest. The fact that PMF only needs to collect changed data speeds up collection, allowing PMF to potentially collect over bandwidth constrained mediums (such as mobile broadband), and allows PMF to immediately report on device integrity without having to address what file may have changed on the device.

PMF automates the generation of certain views into the collected data in support of differential analysis. PMF can generate a heat map of the changed data on each of the device partitions. PMF can gather audit information from the device during the usage period between the initial forensic image and the final forensic image, utilizing a series of forensic processes that target-specific and potentially important device usage information. PMF has the ability to target and visualize all added, deleted, or changed files and directories exclusively during the event of interest. These visualizations supplied during differential analysis help forensics examiners to quickly target the forensically significant data.

Differential Forensics, Post Event, Image Comparison

C2 Using Deep Learning Methods for Forensic Image and Video Investigation

Zeno J. Geradts, PhD, Netherlands Forensic Institute, Laan van Ypenburg 6, Den Haag, SH 2497 GB, NETHERLANDS; and Arnout C. Ruifrok, PhD, Laan van Ypenburg 6, Den Haag 2497 GB, NETHERLANDS*

After attending this presentation, attendees will understand how to search through images based on deep learning methods.

This presentation will impact the forensic science community by illustrating how newly developed algorithms become available for use in forensic science and how they can be applied in casework. The possibilities and limitations will be discussed.

The amount of stored digital images and video material is growing very rapidly since the number of cameras are rapidly increasing, ranging from cameras of Closed-Circuit Television (CCTV) systems to smartphones, computers, and drones in combination with social networks. In complex crime cases or terrorist attacks, the number of images and videos that require processing are often too much to handle in a short period of time. Searching for a certain suspect or tracking persons in video images is often a challenge. To make the pre-processing for further forensic investigation more efficient, there are several approaches for assisting investigators with this process.

Deep learning techniques are now commonly used for searching through many images and videos. In this presentation, an overview is given of methods that are state of the art and which can help the forensic investigation with man-machine interaction. Due to increasing processing power, the deep learning techniques are more feasible to use, and searching in videos and images is easier; however, real-world images are often from different angles, have poor lighting, and other conditions are present that may make the retrieval more complicated.

In this presentation, several examples of deep learning are presented. Several computer vision techniques in combination are presented and the results for a database are also discussed.

More research in deep learning techniques is needed for optimizing the methods that can be used for searching quickly through many hours of video material and classifying the material by user-defined classes. One such example is the search of images of feet or hands that may be useful in child pornography cases in which suspects are only partially visible. Another interesting area is the example of an investigator searching for the brand and model of a camera based on images, where the images of known cameras and models are used as training materials. Another briefly discussed comparison is that of facial comparison.

Additionally, the presentation of retrieval results is a challenge, since most people can only actively search through image material for less than 30 minutes before they become tired and make too many mistakes in the retrieval process. More time is needed for forensic comparison, since it often requires a 1:1 comparison, which takes longer. A good pre-selection is important, and perhaps in the future, the results of deep learning methods can help in finding a likelihood ratio of a certain shape of a feature. Validation of these methods for use in forensic science is important; however, the current research is focused on how deep learning can assist forensic image and video investigation.

Deep Learning, Multimedia, Searching

C3 Discriminating Hacker Techniques by Individual Differences and Techniques of Neutralization

Gregory Bowen, University of Alabama, 4120 Ashington Drive, Birmingham, AL 35242; and Kathryn C. Seigfried-Spellar, PhD*, Purdue University, Computer and Information Technology, 401 N Grant Street, West Lafayette, IN 47907*

After attending this presentation, attendees will better understand the different hacker tools used to commit cyber attacks as well as their relationship to individual differences and techniques of neutralization.

This presentation will impact the forensic science community by being the first study to assess the relationship between hacker tools, individual differences, and techniques of neutralization.

According to Paganini, the top five cyber security threats are: injection vulnerabilities, buffer overflows, sensitive data exposure, broken authentication and session management flaws, and security misconfiguration.[1] In addition, Symantec reported an increase in "trojanized" software updates, malware, ransomware, and social media scams in 2014; in fact, there were 317 million new forms of malicious software created this past year.[2] It is clear that escalating cyber threats and vulnerabilities are a serious concern for both small and large organizations, as well as the private sector and general public.

The term hacking has evolved over the years, but in general it refers to the use of a computer to gain unauthorized access to information systems or to someone who exploits the vulnerabilities of computer networks.[3] Nonetheless, computer crimes are similar to other types of crimes, such as homicide, in that the same crime (e.g., unauthorized access) can be committed, using different tools (e.g., password cracking, sniffing), by offenders with different techniques of neutralization (e.g., denial of injury, denial of responsibility); however, the traditional focus on cybersecurity has been on the creation of better tools, rather than understanding from whom one is being protected.[4-6]

Overall, there are a variety of hacking techniques or tools; however, it is unknown whether individuals are more likely to use multiple hacking techniques (i.e., a generalist) or if they tend to focus on a specific method or tool (i.e., a specialist). In addition, it is unknown whether there is a relationship between individual differences and techniques of neutralization for the different hacking tools/techniques. Thus, the current study will be the first to assess the relationship between individual differences and the types of tools (e.g., a Distributed Denial of Service (DDoS) attack) used by computer hackers along with differences in neutralization (e.g., denial of injury).

This study will be conducted using an anonymous, internet-based survey created in Qualtrics, and respondents will be solicited from Amazon's® Mechanical Turk. Research studies have shown Mechanical Turk may be used to obtain high-quality data inexpensively and rapidly from a diverse participant pool and provides better generalizability than snowball sampling procedures.[7] The survey will assess the prevalence of current tools used to administer various cyber attacks (e.g., DDoS, password cracking tools). In addition, this survey will measure the respondents' personality characteristics and techniques of neutralization.

The results and future implications of the study's findings will be discussed.

Hackers, Personality, Individual Differences

C4 Joint Test Action Group (JTAG) Tool Testing

Jenise Reyes-Rodriguez, BS, NIST, 100 Bureau Drive, Gaithersburg, MD 20899; and Richard Ayers, MS, 100 Bureau Drive, MS 8970, Gaithersburg, MD 20899-8970*

After attending this presentation, attendees will be aware of the importance of tool testing and will have better understand the JTAG tool-testing process conducted within the Computer Forensics Tool Testing (CFTT) project.

This presentation will impact the forensic science community by increasing awareness of the impact tool testing has on informing the forensic community of tool capabilities and limitations. Test reports provide a foundation for toolmakers to improve tools, help users make informed choices, and provide interested parties with an overview of any anomalies found. The presentation will provide an overview of tools capabilities for acquiring and analysis of data recovered from the memory of a mobile device using JTAG and various analysis tools capable of parsing JTAG binary images.

The CFTT project has been researching and testing forensic tools capable of acquiring and analyzing JTAG binary images. This presentation discusses all aspects of the testing process that are critical for producing a test report and the information reported by the analysis tools capable of parsing JTAG binary images.

A summary for the test results of the JTAG acquisition and analysis tools examined will be discussed for each JTAG binary image created for the following test cases: (1) acquisition — acquire mobile device internal memory using supported JTAG hardware/software; (2) subscriber/equipment-related data — review acquired subscriber- and equipment-related information (i.e., International Mobile Equipment Identity (IMEI), Mobile Equipment Identifier/Electronic Serial Number (MEID/ESN), Mobile Station International Subscriber Directory Number (MSISDN)); (3) Personal Information Management (PIM) data — review acquired PIM data (i.e., call logs (incoming, outgoing, missed), calendar entries, memos, Short Message Service (SMS), Multimedia Messaging Service (MMS) (audio, graphic, video), stand-alone files (audio, graphic, video), application-related data, social media-related data (Facebook®, LinkedIn®, Twitter®), internet-related data (browsing history, bookmarks); (4) deleted file recovery — review recoverable deleted data elements; and, (5) Global Positioning System (GPS) data — review data containing GSP longitude and latitude coordinates (routes, pictures, video).

Each test report contains an associated table comprised of two subcolumns that define a particular test category and individual subcategories that are verified when acquiring the internal memory for supported mobile devices within each test case. Each individual subcategory row provides results for each mobile device tested. The results are as follows: (1) as expected — the mobile forensic application returned expected test results — the JTAG tool acquired the contents and the analysis tool reported the data from the binary image successfully; (2) partial — the mobile forensic application returned some of the data from the acquired JTAG binary image; (3) not as expected — the mobile forensic application failed to return expected test results — the tool did not acquire or report supported data from the mobile device successfully; and, (4) Not Applicable (NA) — the mobile forensic application does not support reporting for a specific data element.

The presentation gives an overview of the CFTT process as applied to performing a JTAG acquisition and analysis of the acquired JTAG binary image.

The test reports are available from the Department of Homeland Security Cyber FETCH web site: https://www.cyberfetch.org/.

JTAG, Mobile Forensics, Digital

C5 Mobile Device Data Population for Tool Testing

Jenise Reyes-Rodriguez, BS, NIST, 100 Bureau Drive, Gaithersburg, MD 20899; and Richard Ayers, MS, 100 Bureau Drive, MS 8970, Gaithersburg, MD 20899-8970*

After attending this presentation, attendees will be aware of the importance of populating and documenting the internal memory of mobile devices in preparation for tool testing and will better understand the mobile device data elements and various data population techniques.

This presentation will impact the forensic science community by increasing awareness of the impact the tool testing process has on informing the forensic community of tool capabilities and limitations. Test reports provide a foundation for toolmakers to improve tools, help users make informed choices, and provide interested parties with an overview of any anomalies found. This presentation will provide an overview of techniques for populating and documenting the internal memory contents of mobile devices used for testing mobile forensic tools.

The Computer Forensics Tool Testing (CFTT) project has been researching and testing forensic tools capable of acquiring and analyzing mobile device forensic tools. This presentation discusses all aspects in preparation for testing tools critical for producing a test report.

Techniques for documenting and populating the internal memory for the following data elements will be discussed: (1) subscriber/equipment data — International Mobile Station Equipment Identity (IMEI), Electronic Serial Numbers/Mobile Equipment Identifiers (ESN/MEID), Integrated Circuit ID (ICCID), and Mobile Station International Subscriber Directory Number (MSISDN); (2) address book/contacts — contact name, number, and contact metadata; (3) Personal Information Management (PIM) data — databook, calendar, memo entries; (4) call logs — incoming, outgoing, missed calls, and call log metadata; (5) Short Message Service (SMS) messages — incoming, outgoing, drafts, and SMS message metadata; (6) Multimedia Messaging Service (MMS) messages — incoming, outgoing, drafts, picture, audio, and video MMS messages; (7) stand-alone files — graphic, audio, and video; (8) application-related data — native mobile device applications; (9) social media-related data — Facebook®, Twitter®, and LinkedIn®; and, (10) Global Positioning System (GPS) -related data — longitude/latitude coordinates for routes, checking-in, geo-tagged photos, and videos.

When testing mobile device forensic tools, it is advantageous to possess knowledge of the internal memory contents of the mobile device(s) used. Documentation of the internal memory contents provides the tester with the ability to determine if the forensic application is acquiring and reporting data completely and accurately. Techniques covered in the document are as follows: (1) email account data syncing: — populating the internal memory of a mobile device by pairing and syncing data contents (e.g., contacts, calendar entries, stand-alone files, etc.); (2) Wi-Fi data transfer — populating the internal memory of a mobile device with Wi-Fi capabilities over an internet-connected router; (3) Personal Computer (PC) synchronization — PC sync software provides the user with the ability to transfer data elements from a PC to the mobile device; and, (4) Bluetooth® data transfer — data transfer between two mobile devices that provide Bluetooth® data transfer facilities.

This presentation provides an overview of populating the internal memory of mobile devices in preparation for the CFTT testing process.

The mobile device data population setup guide is available from the CFTT web site: https//www.cftt.nist.gov/mobile_devices.htm.

Mobile Forensics, Digital, Tool Testing

C6 Defining, Measuring, and Mitigating Errors for Digital Forensic Tools

James R. Lyle, PhD, NIST, 100 Bureau Drive, MS 8970, Gaithersburg, MD 20899*

After attending this presentation, attendees will understand some of the limitations and constraints when trying to establish error rates for digital forensic tools.

This presentation will impact the forensic science community by increasing awareness in the community regarding error mitigation strategies that should be used instead of error rates to establish the reliability of digital tools. This presentation will also aid forensic practitioners in recognizing that asking about error rates of digital tools is asking the incorrect question.

Extraction of digital evidence from digital systems is dependent on software to interpret and present relevant data. The courts need assurance that any testimony based on software is scientifically sound and reliable. The *Daubert* guidelines list testing and establishing an error rate as two criteria for the court to consider before deciding admissibility of evidence in court.

In the context of *Daubert*, *error rate* has more the meaning of statistical Type I and Type II errors (i.e., rates of false positive and false negative decisions for matching questions such as: (1) is a sample from a suspect a match to a sample found at a crime scene?; and, (2) is a sample found at a crime scene a match to an item in a data base?)

These matching questions come up in several contexts (e.g., DNA, tool marks, finger prints, etc.). The answer to these questions can exclude a suspect from further consideration or identify a new suspect for closer investigation. Matching questions usually have a random component and can be treated as a statistical hypothesis test with false positive and false negative error rates that can be computed and stated.

These questions are also seen in some situations in digital investigations, such as using cryptographic hashing algorithms to determine if two files match. Hashing reduces an arbitrary length file, possibly quite large, to a short fixed length (128 bits for MD5, 512 bits for SHA3-512) hash value. Error rates can be constructed for hash algorithms: (1) if hashes differ, then the files differ; error rate is zero; and, (2) if hashes match, the chance that there is a hash collision (different files with the same hash) is 1 in $2^{n/2}$, where n is the hash length.

These error rates contribute to satisfying the question (of concern to *Daubert*) of the reliable scientific basis for using hashing to identify file matches; however, hashing illustrates that there are more issues to consider. For digital forensic tools, the implementation must also be considered. Errors in an implementation are not usually statistical in nature and are often triggered by a combination of non-random factors. Unlike elements of DNA within a human population that are stable and change slowly over time, the factors that are relevant to digital evidence change with the pace of technological evolution.

This talk will address how to define error for digital forensic tools, how to use tool testing to identify tool behaviors that are relevant to an investigation, and how to use the knowledge gained from tool testing to mitigate incorrect tool behaviors.

Digital Evidence, Software Testing, Error Rate

C7 Google® Chromebook™: Evaluation of Forensic Methods for Data Extraction

Marcus Rogers, PhD, Purdue University, 401 N Grant Street, West Lafayette, IN 47907; and Yoshitaka Takase, MS*, National Police Agency of Japan /Purdue University, 401 N Grant Street, West Lafayette, IN 47907*

After attending this presentation, attendees will be more familiar with the various forensic methods for extracting data for Google® Chromebooks™. The pros and cons of each method will be discussed.

This presentation will impact the forensic science community by providing information on data storage locations of Google® Chromebooks™ and how evidence can be located and preserved.

The number of Chromebook™ unit shipments has increased in recent years and this increase is expected to continue; correspondingly, more devices could potentially become objects of forensic examinations in various cases. Computers using Google® Chrome™ OS are highly dependent on being connected to the internet. Therefore, they usually contain a relatively small on-board storage capacity; the users are required to use the Google® Drive cloud storage. These systems also use primarily web-based applications.

The current research focuses on understanding the data extraction methods for Chromebooks™ in a laboratory or on site. Three empirical studies were conducted (using a typical case scenario) that focused on settings information and files related to the Chromebook™ device. The first study's objective was to determine the different settings information each user could show on the screen; the users were a Guest user and a Google® account user who was registered as an owner. It was determined that the latter user could show more information. The second study's objective was to determine methods for extracting files from the limited internal storage. The methods tested included manual extraction, designated file extraction, logical extraction, and physical extraction. It was found that manual extraction and designated file extraction were the best methods. Last, the research looked at the preservation of metadata and file integrity as a result of the file extractions from: (1) local drive; (2) cloud drive; and, (3) attached storage media. The results indicated that the "Files application" was a practical method for copying the files to an external drive attached to the Chromebook™, as the modified dates were not altered; however, when using Windows® Explorer or forensic software, the time stamp was interpreted differently. The time difference was the same as the time-gap from Universal Time Coordinated (UTC) (1-hour-gap between standard time and daylight savings time). The research concluded that with Google® Chromebooks™, manual extraction (e.g., taking screenshots, pictures, or notes) maintains the metadata the best and should be considered as part of any standard operation procedure for conducting forensic examinations and analyses of these devices.

Chromebook™, Digital Forensics, Electronic Evidence

C8 Case Study: Snapchat™ Picture Recovery From Mobile Device Unallocated Space

Joseph L. White, MS, US Army Criminal Investigation Laboratory, Digital Evidence-CFI, 4930 N 31st Street, Forest Park, GA 30297*

After attending this presentation, attendees will expand their general understanding of the value of utilizing multiple forensic tools and techniques to recover deleted graphical content from mobile devices, specifically those utilizing the Snapchat™ application, which is designed to not retain multimedia content.

This presentation will impact the forensic science community by providing an overview and example of picture recovery procedures utilized when recovering deleted Snapchat™ pictures from mobile devices utilizing multiple forensic analysis tools and techniques.

Forensic analysis of mobile devices is one of the most quickly evolving areas of Digital and Multimedia Sciences (DMS). With the development and release of mobile devices occurring at a very rapid pace, Digital Forensic Examiners (DFEs) and mobile forensic software companies are faced with the task of determining how to extract and interpret data from the constantly evolving hardware and software of mobile devices. As each new iteration of mobile device and/or mobile device Operating System (OS) is released, it must be determined how to not only extract data from the device, but how to convert the raw data into a format that makes sense to the end user. The use of mobile device applications, or apps, further complicates data analysis of mobile devices. Not only is the base OS of mobile devices under constant development, but individual application developers release and update apps at a surprising pace.

Snapchat™ is a mobile device application that allows users to send and receive multimedia content, such as pictures and video, between specified individual contacts. The transferred multimedia is termed a "Snap." Settings within the sender's Snapchat™ application determine how long the sent content will be viewable on the receiver's mobile device, from one to ten seconds. After the time limit has expired on the receiver's device, the content is allegedly erased. Security features of the Snapchat™ application are also designed to prevent users from taking screen captures of received content through other mobile device applications.

This presentation will discuss these issues through the results of an examination of an Android™-based mobile device submitted for examination to the United States Army Criminal Investigation Laboratory (USACIL) in a case involving the Snapchat™ application. The mobile device submitted to the USACIL belonged to an individual accused of soliciting nude photographs from underage girls through the Snapchat™ application. The accused admitted to sending and receiving content through Snapchat™, but insisted the received content did not contain underage nudity. The actual content of the Snapchat™ pictures became vital to the case. Joint Test Action Group (JTAG) data extraction resulted in a copy of the full device memory for analysis. Initial analysis indicated several snaps were received from the user names utilized by the young girls using the Snapchat™ application, but none of the content was viewable using the default settings of traditional mobile forensics software. Multiple forensic software packages were utilized in an attempt to recover the deleted content. Several illicit pictures apparently depicting the underage girls were eventually recovered from the unallocated space of the mobile device and provided for investigative agency review.

The opinions or assertions contained herein are the private views of the author and are not to be construed as official or as reflecting the views of the Department of the Army or the Department of Defense.

Snapchat™, Data Recovery, Digital Evidence

C9 Development of a Portable Mobile Phone Forensic Acquisition and Analysis Toolkit Utilizing Open Source Tools

Kelsey L. Wilkinson, BS, 1024 8th Street, Apt 5, Huntington, WV 25701; Robert J. Boggs, West Virginia State Police Digital Forensics Unit, 1401 Forensic Science Drive, Huntington, WV 25701; Joshua L. Brunty, MS*, Marshall University, 1 John Marshall Drive, Huntington, WV 25755; and Terry Fenger, PhD, 1401 Forensic Science Drive, Huntington, WV 25701*

After attending this presentation, attendees will understand the usefulness of a Raspberry Pi™ and open source tools for mobile phone acquisition and how to assemble a portable device using these tools.

This presentation will impact the forensic science community by demonstrating the possibility and effectiveness of analyzing mobile phones in a simple and affordable way. Using open source tools and a Raspberry Pi™ allows individuals to modify the device for their specific needs.

The Raspberry Pi™ was developed by The Raspberry Pi™ Foundation, a non-profit organization dedicated to educational charity. Since its release in 2012, the Raspberry Pi's™ use in the digital community has grown steadily. This small, credit card-sized computer allows people to develop and create their own projects and uses for the device beyond its intended concept of learning programming in the classroom.[1] Many forensics applications of this device have developed over the years as well, including penetration testing, surveillance, and network forensics.[2,3] The use of the Raspberry Pi™ 2 Model B to construct a small device with a touchscreen for mobile phone acquisition was researched. Using a Raspberry Pi™ and open source tools for acquisition could increase efficiency, while greatly lowering the cost for digital forensic laboratories.

Commercial tools have dominated mobile phone analysis in digital laboratories for years. Commercial tools are expensive and are not perfect — they can still miss data. In addition, some mobile devices are not supported by commercial tools. Open source tools are free and available to everyone; there is no need for licensing fees each year, which can cost a laboratory thousands of dollars. Since the programming script is open source, bugs or issues with the tool can be found and fixed quickly by users. Also, the open source feature allows examiners to modify and customize their forensic tools to their specific needs. The proprietary nature of commercial tools has made it difficult to explain and demonstrate the process of acquisition in court. With open source tools, the source code can be presented during trial.[4,5] A noted disadvantage of many open source tools is the use of the command prompt; however, some open source tools have added user-friendly Graphical User Interfaces (GUIs), such as Autopsy® (for Sleuth Kit®) or Development Environment For Tutorials (DEFT).

A simple device was developed for less than 300 dollars, utilizing both a 3D printed case and a small pelican case design. A ROBO 3D™ printer was utilized for the 3D printed version. An ARM7™-compatible operating system was loaded onto the Secure Digital (SD) card, and several open source tools with easy-to-use GUIs were tested for use with the device. Chosen open source tools were then compared to commercial tools for both Android™ and iOS® operating systems. The design, items, and development of the operating system used to create this device will be discussed in this presentation, as well as the results found during comparison studies. With further research and continued development of mobile phone forensic tools and GUIs, open source tools may prove to be a useful addition to digital forensic examiners' toolkits in the near future.

C10 Forensic Analysis of Digital Audio File Structures and Formats

Catalin Grigoras, PhD, 1020 15th Street, Ste 8I, Denver, CO 80202; and Jeff M. Smith, MS, National Center for Media Forensics - CU Denver, 1150 10th Street, Ste 177, Denver, CO 80217*

After attending this presentation, attendees will better understand the process for building and deploying a database of audio samples for forensic purposes, specifically for use in the analysis of multimedia metadata, its structure, and characteristics of file formats.

This presentation will impact the forensic science community by disseminating results from the mass analysis of audio files in the Waveform Audio File Format Pulse-Code Modulation (WAV PCM) format produced/prepared by various recorders and software editors.

This presentation describes an extended study on the WAV PCM file structure and format analysis for forensic purposes. In conjunction with other analyses largely involving time and frequency domain measurements/plots, a framework for the authentication of digital audio includes analysis of the file structure and format as well as investigation of the suspected recording device itself.[1,2] Forensic audio is now commonly recorded as uncompressed .WAV files on small digital recorders and authentication of this evidence can end up being crucial in the courtroom. It is also common for digital audio recording systems that store data using a proprietary format and/or encoding to use custom software for conversion to WAV PCM. In the interest of authentication and establishing digital provenance of recordings, examples of traces left by different digital audio editors and converters will be presented.

The following table shows an example of the structure analysis results for four digital audio recorders from Alesis®, Olympus®, Marantz®, and Sony®, along with one Toshiba® audio converter. The preliminary results indicate that while some recorders and editors share the same file structure, other recorders and editors create files with additional metadata.

Alesis® PalmTrack	Olympus® DM-520	Marantz® PMD620	Sony® ICD-SX750	Toshiba® DMR-SX1
Ofs: 0 -> RIFF Ofs: 8 -> WAVE Ofs: C -> fmt Ofs: 24 -> data	Ofs: 0 -> RIFF Ofs: 8 -> WAVE Ofs: C -> fmt Ofs: 24 -> olym Ofs: 2D -> dss Ofs: 38 -> DM520 Ofs: 52 -> *timestamp* Ofs: 3F8 -> data	Ofs: 0 -> RIFF Ofs: 8 -> WAVE Ofs: C -> fmt Ofs: 24 -> bextZ Ofs: 154 -> *timestamp* Ofs: 386 -> data	Ofs: 0 -> RIFF Ofs: 8 -> WAVE Ofs: C -> fmt Ofs: 24 -> JUNK Ofs: 7F8 -> data	Ofs: 0 -> RIFF Ofs: 8 -> WAVE Ofs: C -> fmt Ofs: 26 -> data

Findings from an extensive study will be presented on the structure and format for WAV PCM files created by 31 commercially available digital audio recorders (example brands: Alesis®, Marantz®, Olympus®, Philips®, Roland®, SanDisk®, Sony®, Tascam®, Zoom®, etc.) and 20 processing and converting softwares (e.g., Adobe® Audition, DCLive Forensics, FFmpeg, Goldwave®, Olympus® DSS Player Pro, Sound Forge™, etc.). In addition to these findings, principles that can be followed in the collection and maintenance of reference sample databases for forensic analysis and how to use them in real cases when the suspect recorder is not available will also be shared.

C11 Proposed Analytical Framework for Electronically Frequency/Pitch-Modified Voices

Eliud Bonilla, BS, EB Technologies, LLC, PO Box 102, Kensington, MD 20895; Catalin Grigoras, PhD, 1020 15th Street, Ste 8I, Denver, CO 80202; and Jeff M. Smith, MS, National Center for Media Forensics - CU Denver, 1150 10th Street, Ste 177, Denver, CO 80217*

After attending this presentation, attendees will better understand the main challenges that electronically frequency/pitch-modified voices pose to speaker recognition efforts and the approach the National Center for Media Forensics is proposing in dealing with this issue in forensic environments.

This presentation will impact the forensic science community by providing a holistic analytical framework to use when dealing with electronically modified voices within investigative scenarios. Academic researchers and law enforcement personnel will also benefit since the framework will provide guidance in addressing a common core of questions.

The concept of the human voice as a reliable biometric signal is rapidly being accepted and implemented in today's society. State-of-the-art call centers are increasingly incorporating Automated Speaker Recognition (ASR) technologies in an effort to enhance customer service and minimize identity theft. In the forensics realm, ASR has been accepted in many European courts and may also be accepted in United States federal courts in the not-too-distant future; however, ASR is relatively fragile due to its dependency on the frequency dimension of the voice while not incorporating higher layers of information such as prosody and accents. It can be degraded by a number of inter-/intra-speaker characteristics, in addition to multiple variables along the signal chain.

Purposely modifying the frequency/pitch of a voice by electronic means is an effective counter-forensic measure. It is most often implemented to mask the identity of an individual. Its use can be considered legitimate when used to protect the identity of a witness in a television interview or as part of a law enforcement investigation; however, it can also be used to protect the identity of individuals committing crimes ranging from classic scenarios such as phone calls for ransom requests to recording video/audio messages inciting violence.

Electronic frequency/pitch modification impacts various common forensic analysis methods. Vowel spaces are distorted, thus neutralizing their use by phoneticians. Moderate changes degrade Likelihood Ratio (LR) scores in ASR systems while aggressive changes induce additional errors by distorting the format-frequency relationships outside of normal expected ranges.

The proposed analytical framework addresses four key questions that need to be answered in a satisfactory manner if the analysis is to have practical impact on investigative efforts. First, has the voice actually been electronically modified? Second, is the modification method or algorithm known? Third, are the settings of the method or algorithm known? Fourth, are the modifications reversible in order to enable conventional forensic voice comparison methods?

Attendees will be presented with a flowchart and guidelines that will facilitate incorporating future research in a holistic manner.

Voice Modification, Automated Speaker Recognition, Forensic Voice Comparison

C12 Age Estimation of Adolescents Using Eye Measurements From Various Angles in Videos

Neeka M. Parker, 932 1/2 12th Avenue, Huntington, WV 25701; Joshua L. Brunty, MS, Marshall University, 1 John Marshall Drive, Huntington, WV 25755; Robert J. Boggs, West Virginia State Police Digital Forensics Unit, 1401 Forensic Science Drive, Huntington, WV 25701; and Terry Fenger, PhD, 1401 Forensic Science Drive, Huntington, WV 25701*

After attending this presentation, attendees will understand how to use eye measurements to estimate the age of an individual in a digital video, even when the eyes are viewed from an angle rather than from directly in front.

This presentation will impact the forensic science community by providing information about how the angle at which an image of a face is taken can affect the measurements of that face and their usefulness in estimating age. This is particularly relevant when looking at pictures of people who appear to be teenagers and pre-teens, such as with potential child pornography. The appearance may be natural, but it may also be due to makeup, posing, clothing choice, or filter technologies available when taking a picture of oneself — also known as a "selfie." By relying on measurements of features of the face, including the eyes and pupils, rather than appearance age, the age of an individual can be estimated with fewer hindrances.

Due to the prevalence of social media and devices like smartphones, "selfie" photographs have become extremely popular. These and other images could be part of evidence in a criminal investigation. Any such images can be taken at any camera angle relative to the front of the face. If the age of the individual in the photograph is in question, it becomes necessary to have a way to estimate the person's age regardless of angle.

Institutional Review Board (IRB) approval was obtained in order to use human subjects. The target age group of participants was 11 years to 19 years old, with those less than 18 years of age needing documented parental permission and child assent while those 18 years of age and older only required documented consent. Due to the fact that the pupil is affected by many variables, including mood, medication, and lighting, images were taken under controlled conditions with the illuminance of the room documented. Participants were asked for their birthday and other general demographic information, as well as basic questions regarding mood, medication, and eye problem history. Photographs were taken using a Nikon® D3100 digital camera and Apple® iPad® iOS® Version 7.1.2. A set of two to four photographs was taken with the participants sitting 1.5 meters from the digital camera holding a forensic evidence ruler: one photograph was taken with the participant looking past the camera generating a spontaneous gaze and one was taken with the subject looking at the camera with an attentive gaze; an additional pair of photographs was taken if the participant wore glasses to produce images both with and without glasses. The participants were then asked to take a "selfie" and a short video using the iPad®, with the distance at which these were taken documented. Images were analyzed using Adobe® Photoshop® CS6, while videos were additionally analyzed using Adobe® After Effects®.

Nikon® images were analyzed and the data compared with the formulas given in MacLachlan and Howland.[1] Stills from the videos were analyzed to determine the angle relative to a reference point. The measurements made in these stills were analyzed for a connection to both the angle and the age of the participant.

Age Estimation, Visual Biometrics, Digital Video

C13 The Use of Photo Response Non-Uniformity (PRNU) Patterns for the Comparison of Online Videos on Social Media

Zeno J. Geradts, PhD, Netherlands Forensic Institute, Laan van Ypenburg 6, Den Haag, SH 2497 GB, NETHERLANDS; and Rick Cents, BS, Netherlands Forensic Institute, Laan, Den Haag 2497 GB, NETHERLANDS*

After attending this presentation, attendees will learn that camera identification with online videos should be well validated. In several instances, the wrong conclusion may be drawn by using this method.

This presentation will impact the forensic science community by illustrating how video compression may influence PRNU patterns for camera identification.

It can be important in a forensic investigation to determine the source camera which is used in the recording of specific movies; however, it can also be important to determine how many cameras are used in the recording of movies which are posted on social media platforms such as Facebook® or YouTube®. This research focuses on the use of PRNU patterns in online videos for the determination of the number of cameras used to record the given movies. PRNU is a type of noise present in a picture and video that is caused by the different reaction of pixels to light. Subsequent pixels should have similar values, but this is not always the case due to the manufacturing of the cameras. The PRNU pattern is used for camera identification and can be useful in, for example, child pornography or movie piracy cases. It can also be important to compare multiple online videos to determine how many cameras are used in the recording of specific movies.

Different cameras were tested to determine if it is possible to separate between movies recorded with the same camera and movies recorded with a different camera. The movies were first compared before they were uploaded to YouTube® and Facebook® and the results demonstrated that it was possible to distinguish between movies recorded with the same camera and movies recorded with different cameras. The videos were uploaded to YouTube® and Facebook® and were downloaded again to perform the same comparison. The results revealed that there was a difference in the PRNU pattern which was extracted from those movies. This was probably caused by the extra compression applied by the online platforms. The comparison between the movies demonstrated different results per camera. It was possible for the videos uploaded to YouTube® to distinguish between movies created with the same camera and movies recorded with a different camera when the Canon® Powershot® SX210 IS was used; however, it was not possible in two other models tested. The Canon® camera also provided the best results for the Facebook® videos, but 6 out of the 25 movies delivered an incorrect conclusion and this error rate was even higher in the other cameras. This shows that the compression applied by the online platform has much influence on the PRNU pattern. More research should be performed to optimize the current algorithms for the use of PRNU patterns in online videos.

PRNU, Camera Identification, Social Media

C14 Source Identification of High-Definition Videos — A Forensic Analysis of Downloaders and YouTube® Video Compression Using a Group of Action Cameras

Zac P. Giammarrusco, MS, 3338 Depew Street, Wheat Ridge, CO 80212; Catalin Grigoras, PhD*, 1020 15th Street, Ste 8I, Denver, CO 80202; and Jeff M. Smith, MS*, National Center for Media Forensics - CU Denver, 1150 10th Street, Ste 177, Denver, CO 80217*

After attending this presentation, attendees will understand how YouTube® video compression works and how it can affect different types of high-definition video analysis.

This presentation will impact the forensic science community by teaching investigators how to interpret and analyze video when the origins are on YouTube®.

This presentation addresses the effects of YouTube® on source camera identification while seeking to quantify the amount of change that can occur during the conversion process. It is well understood that YouTube® re-encodes all video uploaded to the site, which has several implications for forensic authentication analysis.[1] The testing material described in this study was comprised of 11 different GoPro® cameras and three different downloader tools.

Video cameras are a large part of today's mainstream society, where many people feel the need to record and share their life's experiences. YouTube®, created in 2007, has become the most popular host of internet videos from around the world with an estimated one billion unique monthly users.[2] YouTube® is localized in 61 countries and across 61 languages. More than 100 hours of video are uploaded every minute. These videos can contain important information about a crime, or event, that might have occurred. For example, in September of 2014, the terrorist group called the Islamic State of Iraq and Syria (ISIS) released a set of videos on YouTube® that portrayed the beheadings of American and British citizens. These videos were called into question, and their authenticity needed to be determined. It is the job of the forensic investigator to determine if a particular video in question is a complete and accurate representation of what it purports to be.

This research describes a variety of established image authentication techniques used to determine the origin of a video. The underlying framework of YouTube® is addressed, including how it works, and the effects it can have on a video in question. The research then describes and compares three tools that can be used for downloading YouTube® videos in addition to how the test data was acquired. The structure and source identification techniques are presented using the test results.

If a video is called into question, and a reference video database is available, the examiner can look for a match. In a forensic case, it is recommended that a database collected over time, with thousands of cameras and videos, be built to help determine the origin of a video. Since a reference population was available in this research, a threshold and a conclusion can be determined. This is the same principle that should be applied in all forensic cases.

The techniques discussed in this presentation are limited in providing positive proof of camera identification since the number of possible combinations between cameras, their settings, and eventually digital edits and recompressions before uploading to YouTube® or other video hosting services is almost impossible to compute. Due to the number of different variables, a set of conclusions is proposed that can be used within a framework for forensic cases.

Video Analysis, YouTube®, GoPro®

C15 The Authentication of MP4 Video Using File Structure and Metadata

Jacob R. Hall, 379 Mooney Hill Road, Patterson, NY 12563*

The goal of this presentation is to inform attendees about the file structure of MP4 video files, the contents of the multiple containers within each file, and the possibilities and limitations of using this information to authenticate an MP4 file.

This presentation will impact the forensic science community by showing a method of analysis to examine the meaningful components of an MP4 recording and parse them to identify the features of a recording that is consistent with an original recording from the device that was claimed to have created it.

With the widely available nature of smart phones and portable devices capable of recording high definition video, there is an overwhelming need for the ability to answer the basic question: Is this an original recording? Investigators have a responsibility to determine whether a file is authentic or if it has been edited in order to better approach their examination. Using the methods outlined in this presentation, an examiner can make a determination as to whether the file is an original recording. By examining both the structure of the MP4 file and the contents of its metadata, a meaningful decision can be made as to it's consistency with an original recording.

Using the QuickTime File Format specification, many important characteristics of a given file can be determined including the original device time and date stamps when the recording was made and the duration of the recording.

While the QuickTime structure contains a certain amount of useful information, there is a great deal of variability in how this data is stored between different device models and manufacturers. At its design level, there is an inherent need for certain data structures to exist in order to maintain files consistent with the QuickTime standard; however, these variations between device models and manufacturers present a unique opportunity for authentication based on a file's data structure and contents.

Using a collection of exemplar recordings taken from more than 20 devices, a baseline can be determined for how a given device stores the audio and video data. By comparing the file structures of these known original files to the file structures of files known to have been edited, differences in the structure of the file can be observed and shown to be indicative of a recording that is or is not consistent with an original recording. These inconsistencies in the files could include the structure of the file itself, the order and contents of the containers within the file, and the presence or absence of identifying keywords within the files metadata. If a given file has been edited in any way and then saved by a piece of third-party software, traces of this event will be evident in the resulting file.

Video Authentication, Mobile Devices, Forensic Video Analysis

C16 Challenges in Recovering Deleted Data in the Cloud

Robert Jackson, MS, SphereCom Enterprises, Inc, 7900 Sudley Road, Ste 416, Manassas, VA 20109; Richard Austin, MS, Hewlett-Packard, 5555 Windward Parkway, Alpharetta, GA 30004; Martin Herman, PhD, 100 Bureau Drive, MS 2000, Gaithersburg, MD 20899; P.W. Carey, MS, Compliance Partners, LLC, 250 S Grove Avenue, Barrington, IL 60010; and Otto S. Reemelin, MS, CBIZ, Inc, 3101 N Central Avenue, Ste 300, Phoenix, AZ 85012*

After attending this presentation, attendees will have a better understanding of the challenges faced by forensic investigators attempting to recover deleted data and metadata in cloud computing environments.

This presentation will impact the forensic science community by describing research performed by the National Institute of Standards and Technology (NIST) Cloud Computing Forensic Science Working Group, which was established to aggregate forensic science challenges in the cloud environment and to develop plans for measurements, standards, and technology research to mitigate those challenges that cannot be handled with current technology and methods. One of the highest priority challenges is recovering deleted data in the cloud.

Data deletion in the cloud is often based on the deletion of nodes pointing to information in virtual instances. Whether the deletion of the information has been fully achieved needs to be assessed and proven. Pathways for retrieval are dependent on cloud providers offering sufficiently sophisticated mechanisms for access. Recovery of data marked as deleted is difficult since it may get overwritten by another user in a shared virtual environment. The challenge becomes more difficult if the entire virtual environment is also deleted.

Issues in recovering deleted data in the cloud include the huge volume of dynamically and continually changing data; cloud resources previously assigned to the user may be unknown; deleted data are overwritten very quickly; there are multiple locations for any given data (data are moved around multiple servers and storage rapidly); there are likely to be multiple copies of data, leading to multiple deletions of data; and there is uncertainty about the proper owner of deleted data. Other issues include the geographically dispersed "incident scene" and the involvement of multiple organizations in multiple jurisdictions.

One important aspect is the role of end points. End points may contain file remnants, contact information, addresses, etc. that will assist investigators in identifying where the deleted data were stored or processed, and identifying other cloud resources that were provisioned; however, in many situations, such as criminal activity or cyber attacks, the end points that were used by the individual(s) involved will likely be inaccessible to investigators.

This presentation will describe the various characteristics dealing with data deletion in the cloud, the effects of various service and deployment models, technical requirements for recovering deleted data in the cloud, sample use cases that help highlight the challenging issues, and the role of standards and technology. For example, standards are needed for data retention (e.g., backups for live data, Virtual Machine (VM) snapshot images, audit trails, transaction logs) to allow easier development of forensics tools. From a technology perspective, forensic tools exist, but the biggest gap is the "needle in the haystack" issue (i.e., there is such a huge volume of data which is continually and dynamically changing that finding the deleted data, and then being able to attribute it to an individual, is a significant challenge).

Digital Forensics, Cloud Computing, Deleted Data Recovery

C17 Counterfeiting and Counterfeit Deterrence Applications for Imaging Technologies

Joel A. Zlotnick, MSFS, U.S. Department of State, 600 19th Street, NW, Ste 12.601, Washington, DC 20522*

After attending this presentation, attendees will better understand how imaging technologies are used by both counterfeiters and producers of security documents such as passports, visas, identity cards, and birth records, and how understanding the specific workflows used by counterfeiters can point the way to innovative counterfeit deterrence solutions based on the capabilities of imaging processes.

This presentation will impact the forensic science community by connecting the forensic science disciplines of questioned document examination and forensic imaging. As a result, attendees may find unexplored potential for greater cooperation in the areas of hardcopy counterfeit document deterrence and detection.

The forensic science disciplines of questioned documents and forensic imaging may be thought of as opposite ends of a spectrum in which hardcopy casework is in the realm of questioned documents and digital images are forensic imaging problems. Yet many common types of evidence in questioned document casework originate from a chain of analog or digital imaging processes, including (for illustration) the examples of trashmark comparisons for common source determination and examination of faxed or photocopied documents. Similarly, questioned document examiners routinely apply imaging techniques to resolve common casework problems. These include not just specialized techniques like electrostatic imaging for visualization of indented writing and alternate light source photography, but also more fundamental digital imaging techniques such as adjustment of contrast (and many similar enhancements) to scans or digital photographs of physical documents.

This presentation focuses on the relationship between the problems of counterfeiting and counterfeit document examination (usually regarded as questioned document issues) and the workflows used by counterfeiters to manufacture their products (which are unquestionably imaging processes). Counterfeiters possess two basic workflows through which they can manufacture fake documents: (1) a scan-and-print workflow where artwork is captured directly from a genuine document template and printed using process color devices; and, (2) a more involved artwork reorigination process in which the artwork is replicated, often using vector imaging tools, for printing using line art and spot color. The first option is popular with some counterfeiters because of its simplicity, but has limited ability to simulate the finer characteristics of genuine security documents. The second workflow has the potential to produce counterfeits that more closely approximate the artwork of a genuine document, but requires substantially greater skills and resources to accomplish.

This model is a significant oversimplification, since counterfeiters often blend these approaches. Further, it does not capture the complexities of simulating various classes of advanced document security features; however, it does provide a foundation for the idea that document artwork, by itself, plays an important role in counterfeit deterrence if it is used specifically to interrupt one of the two counterfeiting workflows described above. In fact, the important role of security document artwork in counterfeit deterrence is emphasized as sophisticated security feature technologies (such as optically variable devices and color shifting inks) become more widely adopted for non-security applications, which makes these technologies more accessible to potential counterfeiters and brings into question their value as standalone counterfeit deterrence solutions.

The basic techniques of counterfeit deterrence are, with certainty, rooted in imaging science. Certain security artwork strategies that are already in common use to combat one or both of the specific counterfeiting workflows described include the use of line art and spot color design, split fountain printing, microprinting, void pantographs, dedicated security halftones, and the use of inks encompassing expanded color gamuts (such as the use of Ultraviolet (UV) -responsive, metallic, or iridescent inks). These foundational security printing techniques are great examples of how inexpensive design strategies can make documents more resistant to counterfeiting; however, this presentation proposes that there is room for further work in this area and will describe some novel counterfeit deterrence concepts that specifically exploit differences between printing workflows used for production of genuine documents and counterfeit documents. The final purpose of this presentation is to initiate further conversation with the imaging science community regarding intractable forensic imaging problems, to determine if those problems can be purposefully extrapolated into the hardcopy printing world to deter counterfeiting.

Counterfeit, Imaging, Document

C18 H.Y.D.R.A. (Hyper Yield Data-Driven Real-Time Analysis)

Anthony Skjellum, PhD, Auburn University, Dept of Computer Science and Software Eng, 345 W Magnolia, 3101 Shelby Center, Auburn, AL 36849-5347; Austin Hancock, BS*, Auburn University, 3101 Shelby Center, Auburn, AL 36849-5347; Janice Canedo*, Auburn University, 3101 Shelby Center, Auburn, AL 36849-5347; and Erby Fischer, Auburn University, 3101 Shelby Center, Auburn, AL 36849-5347*

After attending this presentation, attendees will better understand a dynamic malware detection architecture for forensic science on Android™ devices that is also applicable to Linux®-based systems.

This presentation will impact the forensic science community by verifying and illustrating in detail the steps necessary to derive a data set composed of process control block variables that, when monitored in real time, are capable of identifying malicious behavior within milliseconds of its occurrence. This provides a dynamic architecture for forensic science on Android™ devices and supports live response as well as network defense and continuous monitoring.

Android™ and Linux® malware is an important class of threats to digital systems including mobile phones, tablets, Internet of Things (IoT), and portable devices. In this presentation, the focus is on advancements based on previous work that combines machine learning and process behavior to detect malware dynamically without resort to signature-based or other static methods. This research enables forensics studies of running systems.

Current static detection, including signature-based detection, fail to adapt quickly to the changing nature of malware in mobile devices. This inability to adapt quickly is inefficient at providing malicious behavior analysis, particularly in light of digital forensics. By utilizing a dynamic detection technique, attendees will overcome many of these aforementioned shortcomings. For example, the dynamic technique does not require familiarity with a given sample, knowledge of its signature, nor is it impeded by code obfuscation.

Research conducted recently by Dr. Farrukh Shahzad has shown that the execution behavior of a malicious Android™ application on Android™ 2.3 is markedly different from that of a benign Android™ application. To define execution behavior, a data set was determined by using a custom kernel module to monitor all variables in the Process Control Block (PCB) for an android process. Once a model of malicious behavior was obtained, it could be utilized in real time to classify an unknown application's behavior as malicious or benign.

This study intends to investigate the methodology demonstrated on the legacy system by Shahzad on current Android™ versions (e.g., Android™ 4.3, 4.4, 5.0) further. Dataset investigations from the legacy system will be demonstrated to determine the extent of changes vis-à-vis current Android™ versions. A comparison of the mathematics and methodologies utilized by Shahzad to both Bayesian Classification and Exploratory Data Analysis techniques will be analyzed to determine if they perform equivalently for malware detection.

For mining the data, system processes including core device processes and network performance are considered. Each system process is examined in an effort to find non-trivial correlations. For each correlation discovered, investigations are pursued further in an effort to prove a causation, since not all correlations lead to a causation. Both Exploratory Data Analysis (EDA) techniques and Bayesian classification techniques are explored in order to find causation, if present.

Both the validity and capability of alternative classification techniques on process behavior are covered. The work demonstrates the dynamic nature of the dataset as the Android™ operating system version progresses. The results from this investigation validate and refine a dynamic architecture for forensic science on Android™ devices.

Beyond Android™ and Linux®, the methodology created and advanced in this presentation can be applied in the future to other embedded and mobile operating systems.

Dynamic, Android, Malware

C19 A Comparison of Computer Forensic Tools: An Open-Source Evaluation

Adam Cervellone, BS, 611 22nd Street, Apt 323, Huntington, WV 25703; Robert Price, MS, North Carolina State Crime Laboratory, 121 E Tryon Road, Raleigh, NC 27601; Joshua L. Brunty, MS, Marshall University, 1 John Marshall Drive, Huntington, WV 25755; and Terry Fenger, PhD, 1401 Forensic Science Drive, Huntington, WV 25701*

After attending this presentation, attendees will better understand the capabilities of EnCase® Forensic 6, FTK® 5.6, and the SANS Investigative Forensic Toolkit (SIFT) Workstation 3.0, as well as learning if the SIFT Workstation 3.0 could be used as a viable forensic tool in a laboratory setting.

This presentation will impact the forensic science community by providing a clear and concise breakdown of the capabilities of the leading industry standard tools as well as a popular open-source tool. Very little documented research has been conducted comparing an open-source forensic tool with the industry standard tools; as such, this presentation will add to the research and hopefully encourage other studies.

The world of digital forensics is an ever-evolving field with multiple tools for analysis from which to choose. Many of these tools have very focused functions such as Mac® and iOS® device analysis registry examination, steganography analysis, mobile device examination, password recovery and countless others. Other tools are full-featured suites capable of analyzing a large case with multiple items.[1] The major problem with many of these tools is cost.[2] While they may be robust, they may not be affordable for a smaller laboratory that wants to engage in digital forensics.[3] This research focuses on industry standard forensic software such as: Guidance Software EnCase® Forensic 6, AccessData FTK® 5 as well as SANS' SIFT Workstation 3.0.[4-6] The SIFT Workstation is a freely available open-source processing environment that contains multiple tools with similar functionality to EnCase® and FTK®.[6] This study evaluates the processing and analysis capabilities of each tool. In addition to processing functionality, two other studies were conducted. The first is a virtualization study focusing on the ability of the software to create or help create a virtual machine from an E01 evidence file. The advent of cloud computing would make this an advantageous procedure in digital forensics.[3] The second is a simple cost analysis study. This portion of the research displayed how much a laboratory may have to spend to get a single examiner fully on-line with each tool. While comparison studies between commercially available software have been conducted and published, research comparing industry standard tools with an open-source tool is not well documented.[1]

For this study, mock test cases were created using North Carolina State Crime Laboratory (NCSCL) Mac® Minis and Dell® Latitude D810 laptops. The hard drives contained in these devices were hashed and imaged via EnCase® Forensic 6.19 and fully processed according to NCSCL guidelines in EnCase® Forensic 6.19, FTK® 5.6.3, and the SIFT Workstation 3.0. In addition to evaluating analysis, the tools were also evaluated based on their ability to create a virtual machine from the evidence file as well as on overall cost for a single examiner.[7-9]

This research has shown that the SIFT workstation is a viable option to use as a forensic tool, from a financial and functionality perspective. Its capabilities are vast and are similar to those of FTK® and EnCase® Forensic; however, due to its open-source nature and heavy reliance on the Linux® Terminal and command line, it is advised that only examiners highly skilled in Linux® use the SIFT Workstation for casework in order to maintain its viability.

C20 Integrating a Profile of Frontal Face With Its Mirror Image for Facial Reconstruction

Paramjit Kaur, MSc, Panjab University, Centre for Systems Biology and Bioinformatics, Chandigarh 160014, INDIA; Kewal Krishan, PhD, Panjab University, Dept of Anthropology, Sector 14, Chandigarh 160 014, INDIA; Tanuj Kanchan, MD, Dept of Forensic Medicine, Light House Hill Road, Mangalore, Karnataka 575 001, INDIA; and Suresh K. Sharma, PhD, Panjab University, Centre for Systems Biology and Bioinformatics, Chandigarh 160014, INDIA*

After attending this presentation, attendees will understand the value of computer-generated programs in facial reconstruction when a half frontal profile of the face usually captured in Closed-Circuit Television (CCTV) cameras and other surveillance systems is available for forensic examination.

This presentation will impact the forensic science community by presenting a detailed analysis of the generated computer program, which will help attendees in understanding the concept of using this program for full facial reconstruction.

The face is an important part of the human body that is used to recognize and distinguish one person from a large number of people. This is due to the uniqueness of the human face and the great variability in the features observed in different human faces. Forensic anthropologists and scientists are interested in studying the various features of the face as this is useful for the reconstruction of a human face from an available cranium. Forensic anthropologists and scientists are also interested in establishing the biological profile of the person/deceased, such as estimation of age, sex, race/ethnicity as well as probable stature, in order to have the maximum number of clues for identification of the deceased. In this era of CCTV cameras, facial identification is based upon the comparison of the images obtained from a crime scene; thus, identifying human faces has become an important computer technology. At times with CCTV cameras and other surveillance systems, the complete face is not visible and only half of the frontal facial pose is captured; however, half of the mirror image of the face can be used to reconstruct the complete face of the person in question. In previous studies related to identification or in the field of computers, mirror images have only been used to solve the problem of a non-sufficient training sample and have not been used for full facial reconstruction.

In this presentation, a methodology is presented to generate a mirror image from one facial profile, merging it with the input image to generate a complete face. This procedure is very simple, less time consuming, and computationally efficient. The designed program was tested on a selected sample of five adult females ranging in age from 20 years to 30 years old. The photographs of the participants were taken against realistic backgrounds using standard procedures. The images were processed using IrfanView v. 4.38 software and a novel program was designed using MATLAB® (Version 7.9.0 (R2009B)). The program uses the right frontal profile of the participant's face as input and generates its mirror image. Finally, it merges both the input image and the mirror image to generate the complete face of the individual.

The facial asymmetry cannot be distinguished in the generated images because these images are the result of the mirror image formation of the right profile image of the face; however, even though the differences are discernable between the two types of images (i.e., the generated and the actual images), the faces are recognizable from the reconstructed images. Therefore, the present approach would help to generate a complete facial image in cases in which only one frontal profile (i.e., the left or right side of the face) are available for examination. The proposed methodology would also be useful for improving other facial reconstruction and recognition methods.

Facial Reconstruction, Computer Program, CCTV Captured Images

C21 Performance of Matching Algorithms in Non-Standard Expression-Variant Faces

Petra Urbanová, PhD, Masaryk University, Kotlarska 2, Brno, Czech Republic 611 37, CZECH REPUBLIC; and Igor Chalás, Masaryk University, Dept of Computer Graphics and Design, Faculty of Informatics, Brno, South Moravian Region 60300, CZECH REPUBLIC*

After attending this presentation, attendees will understand the basic principles on which mesh-to-mesh and deep learning algorithms for 3D face recognition are grounded. Attendees will also be more familiar with the performance of 3D-to-3D and 2D-to-3D matching algorithms as tested on expression-variant 3D recordings of human faces.

This presentation will impact the forensic science community by providing insight into current state-of-the-art forensic facial identification and by introducing approaches designed or applicable for processing of 3D faces.

The role of images (Identification (ID) photographs or surveillance videos) in personal identification is sometimes downplayed because image-based forensic evidence is, on many occasions, presented for examination in very poor quality, with non-standard framing, viewpoints, or under unspecified conditions. Furthermore, many images are unsuitable for automatic or semi-automatic face recognition systems due to non-standard poses, occlusion, or facial expressions. Development of 3D sensors, which has allowed recording depth information of human faces, has had a great impact on improving the robustness of facial recognition algorithms. Installations of 3D video surveillance systems and 3D capturing devices built for outdoor use have increased chances of securing 3D images at crime scenes and/or in the course of forensic investigations. 3D technology has been shown to compensate for many of the shortcomings traditionally associated with conventional 2D images and to improve performances of matching systems in personal identification if standard faces are processed; however, this technology becomes less successful if dynamic body features, such as hairstyle, facial hair, and, most importantly, facial expressions are incorporated.

Following previous studies, which indicated that matching 3D records of human faces outperform existing systems based on 2D images if tested on controlled expression-invariant faces, the present study sought to extend the objectives by exploring performance of matching algorithms using non-standard expression-variant 3D faces. The tested dataset was composed of an array of 3D faces with nine different facial expressions, including one with a neutral appearance, collected from 150 participants (for a total of 1,350 scans). For each individual, the array was acquired within one scanning session using the VECTRA® XT 3D imaging system.

Two matching algorithms varying in complexity and computation requirements were tested. The first falls under the rubric of 3D-to-3D image matching and was based on extracting 3D mesh geometry descriptors. The second applied 3D-to-2D conversion prior to computation and was based on a learning algorithm featuring convolution networks. For mesh-based matching, algorithms incorporated into FIDENTIS Analyst, a software application developed specifically for processing 3D faces, were tested. The program utilizes the Iterative Closest Point (ICP) algorithm for one-to-one, one-to-all, and one-to-average registration of 3D faces. Dissimilarity of aligned 3D faces is subsequently expressed via signed and absolute closest vertex-to-vertex distances. One scan per individual was selected randomly and tested against the FIDENTIS 3D Face Database (N~2,100 subjects; www.fidentis.cz). This was carried out repeatedly on the entire tested subset. A match/non-match decision was subsequently made while employing a classification model provided by linear discriminant analysis.

For the second approach, a deeper learning algorithm incorporated in CAFFE framework (caffe.berkeleyvision.org) was adapted. Prior to processing, 3D textured meshes were converted automatically into 2D color images (resolution 256 by 256 pixels) accompanied by corresponding depth maps using a simple in-house converter (Face viewer). In order to train the system, the dataset was split into training (75%) and testing (25%) subsets. To classify the images as matching/non-matching, the Berkeley Vision and Learning Center (BVLC) Reference CaffeNet classification model was employed. In both instances, performance of the tested algorithms was assessed by Receiver Operating Characteristics (ROC) curves (cross-validated by repeated random sub-sampling) and expressed in terms of Area Under the Curve (AUC), likelihood ,and odds ratios.

The results showed that both tested approaches were challenged by the presence of facial expressions in the tested data and their performance was poorer than when tested on 3D faces with neutral expressions; however, the deep learning approach proved that it could be very efficient if trained on a very large training dataset and, in a more user-friendly version, could be of help for forensic experts. Both tested algorithms were also shown to possess high demands on hardware and computation time. The work which deals with non-standard 3D images and departs from the recent trends of employing advanced computation and learning techniques may improve methods of facial recognition used in the forensic settings. The main purpose of this presentation is to present these prospects to the forensic community.

3D Face Recognition, Face Expression, Matching Algorithms

C22 On the Need for Social Contract Theory in the Ethics of Digital Forensics

Martin S. Olivier, PhD, University of Pretoria, Computer Science, Pretoria 0002, SOUTH AFRICA*

The goal of this presentation is to describe how professional codes of ethics are based on philosophical notions of ethics, with deontic and consequentialist theories most often seen. Aristotelean virtue ethics are also encountered. This presentation will also indicate that none of these theories provide the subject of a digital forensic examination with sufficient protection. By eliminating these theories and considering the fiduciary duty of digital forensic examiners, it is argued that an ethics theory based on social contract theory best balances the interests of the examiner and the (innocent until proven guilty) examined.

This presentation will impact the forensic science community by indicating that an ethics theory or code of conduct for a forensic examiner not only depends on what one expects from an ethical forensic scientist, but also on the nature of the artifacts examined. The artifacts examined in digital forensic science are often of an intimate nature and deserve to be examined with special care. Social contract theory provides a widely accepted basis to balance the interests of the various parties in an examination. It is hoped that these insights will lead to the establishment of a code of conduct for digital forensic examiners that reflect the special nature of examined artifacts.

The conclusion of this presentation is that a code based on social contract theory is not only indicated by the argument provided above, but will also assist in providing practical moral guidance. It is argued that such a code will necessarily be one that is not a mere list of good practices, but one that provides principles that need to be applied (or interpreted in a given situation) to provide moral insight.

Professional ethics typically manifest as normative guidelines describing the proper conduct expected from professionals. Professional status stems from extended education and training in a specific discipline that permit an individual to execute specialized tasks in society, where members of the society, due a lack of similar skills, have no option but to rely on the work of the professional. Codes of conduct are derived from various ethics theories with (professional) duty, (utilitarian) fairness, and notions of professionalism (virtues) usually all present to a greater or lesser extent. Such codes typically also include some requirements of allegiance to the profession as well as submission to sanctions by professional bodies. Codes worth exploring for such examples range from ancient texts, such as the Hippocratic Oath, to more modern codes in the forensic science domain, with prominent examples being those of the American Academy of Forensic Sciences (AAFS), the American Society of Crime Laboratory Directors (ASCLD), the Global Information Assurance Certification (GIAC), and the SANS Institute.

Distilling professional codes of conduct to their bare essence usually yields two elements: (1) the need to act with integrity; and, (2) the need to act to the best of one's ability where the ability is expected to be at a very high level — a level that justifies the professional epithet. This presentation argues that this second requirement is insufficient for forensics, in general, and digital forensics, in particular.

The basis of the presentation's thesis is the fact that forensics is a family of applied sciences. Ethics in science is a topic that has been studied from multiple perspectives: impact of research on participants; potential scientific bias of researchers (due to commercial, authority-related, gender-based, and other influences that the researcher may be unaware of); and the expected behavior of the scientist. This presentation takes its primary cue from this third category. Again, once distilled, it is clear that the primary demand on the scientist is to act with integrity; however, the paper argues that there are subtle differences between the expectations of integrity in the scientific and professional contexts. The forensic scientist has to conform to both flavors of integrity. Finally, the subject matter of the digital forensic scientist adds a third flavor of integrity that constrains his or her actions.

Above, the phrase "flavor of integrity" was used to imply that the concept of integrity — nebulous as it may be — remains the same; however, what one emphasizes about it may differ from instance to instance. The (Platonic) ideal form of science is one that searches for the truth above everything else. Hence, integrity in a scientific endeavor refers to choices that seek the truth above all else. Note that scientific integrity does not require the achievement of this ideal (which is impossible), but a dedication to seeking truth. At first glance, the dedication to truth seems that an imperative approach to forensic ethics is appropriate; however, the German philosopher Immanuel Kant showed that autonomy is required for a deontic approach. While the forensic scientist should not be constrained in seeking the truth, this scientist is bound by science — hence, total autonomy is not an option. Similarly, seeking truth is a virtue that suggests an Aristotelian approach; however, Aristotle's focus on a golden mean is inappropriate. Similarly, balancing outcomes in consequentialist theories renders utilitarianism impractical.

This presentation suggests that the difficulty in finding a home for forensic science in the best-known classical ethics theories stems from the fact that forensics potentially exerts control over the individual by helping to determine guilt or innocence (keeping in mind it is not only the guilty who stand accused of wrongdoing) and this power may be sovereign. This suggests a social contract theory as a key element in determining the appropriate ethical behavior of forensic science (and, ultimately, the forensic scientist). Given that John Rawls's seminal work already straddles constraint of power through the social contract theory and the domain of ethics, this approach is an obvious theory here.

Forensic power increases in the case of digital evidence. While forensic science makes truth claims related to human beings, everyday digitalization causes digital forensic power to permeate the individual's essence. This is cause for the clear balance of power and purpose.

Professional Ethics, Digital Forensic Artifacts, Social Contract Theory

C23 An Efficient and Effective Forensic Analysis Approach for the Internet of Things (IoT)

Anthony Skjellum, PhD, Auburn University, Dept of Computer Science and Software Eng, 345 W Magnolia, 3101 Shelby Center, Auburn, AL 36849-5347; Ankit Kumar Singh*, Auburn University, Dept of Comp, Sci and Software Engineering, 3101 Shelby Center, Auburn, AL 36849; and Janice Canedo*, Auburn University, 3101 Shelby Center, Auburn, AL 36849-5347*

After attending this presentation, attendees will better understand an IoT Forensics Framework that consists of both device and network-level forensics.

This presentation will affect the forensic science community by providing direction toward addressing changes in digital forensics with the introduction of IoT devices. Identification of the limitations of existing, early models for IoT Forensics with a new, resource-conscious paradigm offered for IoT Forensics combines concepts from continuous monitoring (network forensics) and computer forensics.

The IoT is an emerging distributed network of billions of smart devices ("things") that possess the ability to communicate and exchange data. The number of such devices is expected to increase rapidly, resulting in generating massive amounts of data. Considering these factors, Digital Forensic (DF) investigations will face new challenges arising from the ubiquitous use of the IoT in society. DF investigation processes including identification, collection, organization, and presentation in the context of the IoT devices must be understood, planned-for, and recognized as significantly different than the processes for common devices such as smart phones, tablets, servers, and Personal Computers (PCs).

Existing procedures used for handling DF investigations aren't sufficient for the IoT. Some investigators have already recognized this. For example, one recent model for the IoT-related crime investigations, Forensic Aware IoT (FAIoT) described by Hasan et al., requires that all registered IoT devices be monitored and that they store potential evidence in a shared repository.[1] A second model, the Forensic Edge Management System (FEMS) advanced by Oriwoh et al., proposes the use of a smart device that would be used for real-time monitoring and forensic services within a Smart Home IoT environment.[2]

While current models focus only on a device-driven architecture, this study's strategy is to create an IoT Forensics Framework that includes device and network forensics. The IoT devices will be connected and communicate through a network; therefore, identifying forensic elements and retrieving relevant evidence from the network is vital. To group similar events efficiently, investigative techniques are covered using data mining techniques including Bayesian Classification.

Overall, a systematic analysis approach geared toward handling IoT-related forensic investigations is needed. An IoT Forensics Framework is proposed that will impact all stages of forensic investigations and make the IoT domain more forensic-ready. Systematic trade-offs of static and dynamic resource overheads will be shown in order to achieve sufficient degrees of forensic fidelity. An argument that all IoT Forensics is best implemented as continuous monitoring, includes forensics for devices as well as the associated networks, uses secure protocols for communication between FEMS smart devices and other devices, and has small events grouped as super events shall be made clear to the attendees.

ENGINEERING SCIENCES

D1 Richard III Discovered: The King's Remains

Sarah V. Hainsworth, PhD, University of Leicester, Dept of Engineering, Leicester LE1 7RH, UNITED KINGDOM; Guy N. Rutty, MD, University of Leicester, Forensic Pathology Unit, Robert Kilpatrick Bldg, Leicester LE2 7LX, UNITED KINGDOM; Jo Appleby, PhD, University of Leicester, Archaeology & Ancient History, Leicester LE1 7RH, UNITED KINGDOM; and Alison L. Brough, BS, University of Leicester, Forensic Pathology Unit, RKB, Leicester Royal Infirmary, Leicester LE2 7LX, UNITED KINGDOM*

After attending this presentation, attendees will understand how modern forensic techniques used for tool mark analysis can be applied to determining how injuries were sustained to a 500-year-old skeleton.

This presentation will impact the forensic science community by demonstrating how techniques from forensic engineering science, forensic pathology, and archaeology have been combined to understand the wounds and weapons used to cause the injuries found on the King's skeleton.

Richard III was King of England between 1483 and 1485. In 1485, King Richard III rode with his army from Leicester to fight against Henry Tudor, later crowned King Henry VII of England. The battle was fought at Bosworth Field approximately 20 miles from Leicester. Bosworth was a short battle lasting approximately two hours. The battle reached its end when Richard was killed.

Of all the monarchs of England since 839, Richard III was the only one whose final resting place was unknown. One legend had it that his body had been thrown into the River Soar and was lost forever. Other tales told of a church ruin with a plaque on a column claiming to mark his grave.

In 2012, the University of Leicester was given permission by Leicester City Council to excavate a site — a council car park that, from scrutiny of ancient maps, could well be the site of the Greyfriars church where Richard may have been interred.

Despite limited funding and more than 500 years of lost records, the very first trench dug in the car park exposed a skeleton. Two further trenches revealed the outline of the ancient church and confirmed that the skeleton was buried in the choir of the church, a mark of high status. Moreover, the skeleton showed pronounced scoliosis, a curvature of the spine, and evidence of battle injuries.

Carbon dating revealed that the skeleton was of the correct age to be Richard III. Mitochondrial DNA testing and a Bayesian statistical analysis demonstrated a conservative estimate of 99.999% confidence that the skeleton was indeed that of Richard III. The results of the find were announced by the University of Leicester to worldwide media coverage in February 2013. In the United States, this find is often referred to as "the King in the Car Park."

There were 11 injuries to the skeleton: 9 to the skull, 1 to the rib, and 1 to the pelvis. Ten of the injuries were considered peri-mortem while the pelvis injury was most likely a postmortem injury. Three of the injuries to the skull showed evidence of striations from tool marks and tool mark analysis determined that these marks were likely made by the same blade.

This presentation will exhibit the computed tomography and micro-computed tomography images that were taken from the skeleton and explain how the injuries relate to weapons from the period.

This presentation will be relevant to forensic engineers, pathologists, and anthropologists who have an interest in tool mark analysis and the relationship between tool marks and weapons.

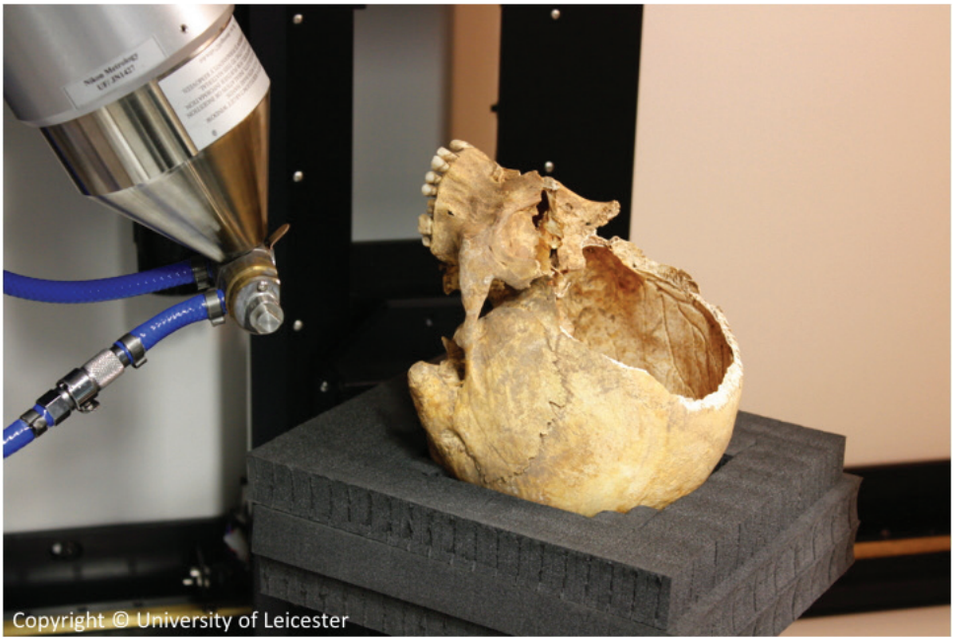

Figure 1: The skull of Richard III mounted in the micro-computed X-ray tomography scanner.

Richard III, Microcomputed X-Ray Tomography, Tool Marks

D2 Measurement of High Temperature and High Humidity Moisture Effects in Football Helmet Elastomeric Energy-Absorbing Padding Performance and Implications for Head Injury Danger

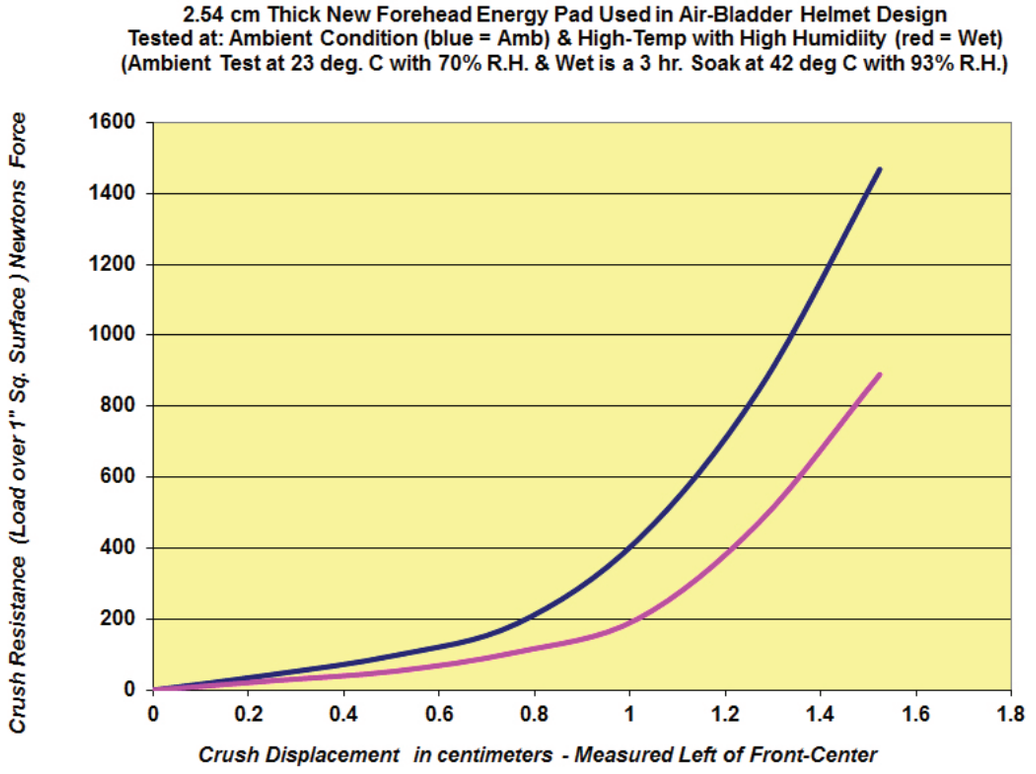
Kenneth J. Saczalski, PhD, 1440 W Bay Avenue, Newport Beach, CA 92661; Mark N. West, BS, Environmental Research & Safety Technologists, 1440 W Bay Avenue, Newport Beach, CA 92661; Todd Saczalski, BSMET, 140 Calle Irena, Sedona, AZ 86336; Joseph L. Burton, MD, 13784 Highway 9, Alpharetta, GA 30004; Paul Renfroe Lewis, Jr., MS, Bioforensic Consulting, 55 Park Square Court, Ste 207, Roswell, GA 30075; and Mark C. Pozzi, MS, Sandia Safety Sciences, 2 Marietta Court, Ste A, Edgewood, NM 87015*

After attending this presentation, attendees will better understand a method for improved scientific evaluation and certification of a football helmet head-impact potential when used in common, but not currently tested, conditions of both high temperature and humidity.

Certification and evaluation of new and reconditioned football helmets should include impact performance evaluations under high temperature and high humidity soak conditions that more realistically replicate early season environmental use conditions. This presentation will impact the forensic science community by explaining how this type of evaluation can be beneficial in forensic science studies and in early phases of helmet design, and in reconditioning of used helmets, so as to assist in the proper selection of energy-absorbing padding that is more resistant to degradation of impact safety performance in the high temperature and high humidity environment.

Publicity on the dangers of concussion and severe head injuries sustained by football players subjected to repetitive head impacts has, rightfully, received much attention in recent years, in a very large part due to the diligent work by medical researchers such as Omalu and McKee; however, there is an important contributing factor related to football head injury, caused by repetitive head impacts, that has received virtually no attention thus far except for the research findings presented in this study.[1,2] That factor deals with understanding the degradation of the energy-absorbing impact characteristics of elastomeric padding materials, used in football helmets, when a player is subjected to head impacts while wearing the helmet during common situations involving both high temperature and high humidity moisture conditions, such as the conditions likely to be experienced earlier in the season when the weather tends to be both hot and humid. Current football helmet performance test certification procedures, such as the National Operating Committee on Standards for Athletic Equipment (NOCSAE) standard, do not have and never have had a test criterion for measuring helmet impact Severity Index (SI) performance when simultaneously subjected to both high temperatures and high humidity above the 90% relative humidity level.[3] The current criteria only require testing with humidity in the range of 25% to 75% levels.

In this study, two types of football helmet elastomeric Energy-Absorbing (EA) forehead impact pad designs were tested Quasi-Statically (QS) and dynamically for evaluation of load-deformation performance and head impact severity when subjected to two different environmental conditions. One environmental series of tests were run with the pads and helmet tested at ambient conditions of 23oC (72oF) and 70% humidity. A second series of tests were run with the pads and helmet subjected to a three-hour soak at 42oC (108oF) and 93% humidity. Both types of EA pads were designed in a "dual density" configuration (i.e., soft foam near the forehead and stiffer foam at the shell side), with the exception that one type of pad was encased in a Vinyl Cover (VC) and the other type had No Vinyl Cover (NVC). Both new and used pads were tested. The EA pads were 2.54cm thick and were compressed to just over 60% of full thickness in the QS tests. The QS tests showed a dramatic drop in load-carrying capability of the forehead pad when tested at the high temperature and humidity condition (see below plot). The result of this "softening" of the pad is that it becomes easier for the helmet pads to "bottom out," leading to much higher impact-load transfer to the head of the athlete.



In addition to the QS EA pad testing, dynamic full-helmet drop-impact tests were also conducted for both of the EA pad types and environmental conditions cited above. The dynamic tests used a NOCSAE head-form and vertical drop impacts into the forehead region of the helmet at impact speed levels of 5.54m/s (i.e., 12.2mph), which is the upper speed level required by the NOCSAE, and 19.05m/s (i.e., 14.2mph), which is closer to the speed of a player who can run 40 yards in just over five seconds). For the 5.54m/s impact level, the helmet with the VC forehead EA pad, when tested under the "ambient" test condition, resulted in an accelerometer peak G reading of 141 and an SI level of 645.7; however, when the helmet with the VC pad was then again tested at the same 5.54m/s impact speed, but after conditioning at the Higher Temperature and Humidity (HTH) conditions, the head form accelerometer reading indicated an increased peak G of 163 and an SI level of 786.4, resulting in a more dangerous 22% increase in the SI when tested at the 5.54m/s impact with the HTH condition versus the "ambient" test condition used for helmet NOCSAE certification. When tested with the NVC forehead EA pad at the 5.54m/s impact, the helmet results demonstrated an increase in the acceleration peak G (approximately 175) and SI measures (approximately 900), but no significant difference in the readings between the ambient and HTH. When tested at the 19.05m/s impact level, the peak G's increased, as expected, and the SI measures also increased up to, and beyond, the NOCSAE standard limit of 1,200 for both environmental conditions and both forehead pad types. It should also be noted that the HTH environmental test temperature and moisture conditions could arise from a player perspiring even if the environment levels are less than the HTH condition.

In summary, the environmentally induced changes in the load-deformation characteristics of the energy-absorbing padding shown in the curve above, and the increase in SI found in the HTH environment helmet testing, suggest that more research and testing should be conducted in the HTH area. Because of the current awareness of the "Concussion-Dangers" associated with football repeated head impact injuries brought to light by researchers such as Omalu and McKee, and because of the fact that many players of all ages play under the conditions of "High Humidity with High Temperature," at least in the earlier part of the season, the importance and need for more testing and certification of helmets under conditions of high temperature with high humidity should be of concern to all.

Football Helmet Testing, Head Injury Severity, High Temperature Humidity

D3 Specimen Age Affects the Fracture Pattern of Immature Porcine Femurs Under Torsional Loading

Patrick E. Vaughan, BS, Michigan State University, Orthopaedic Biomechanics Laboratories, E Fee Hall, Rm 407, East Lansing, MI 48824; Feng Wei, PhD, Michigan State University, 965 Fee Road, Rm A-414B, East Lansing, MI 48824; and Roger C. Haut, PhD, Michigan State University, Orthopaedic Biomechanics, A407 E Fee Hall, East Lansing, MI 48824*

After attending this presentation, attendees will better understand the influences of bone development and rate of twist on torsional failure characteristics of porcine femurs.

This presentation will impact the forensic science community by providing additional information on the use of fracture ratio to help differentiate Accidental Trauma (AT) from Non-Accidental Trauma (NAT) under torsional loading scenarios.

In the current forensic literature, differentiation between an abusive and accidental trauma in children less than three years of age remains challenging. Currently, it is assumed that any trauma incurred by children less than three years of age is frequently NAT, and that any trauma in children less than one year is always NAT.[1] Furthermore, spiral long-bone fractures in young children are challenging cases because there are limited "ground truth" data to help forensic investigators determine the mechanisms of long-bone fracture. A recent study has proposed fracture ratio, defined as the fracture length in a lateral radiograph over the diameter of the bone, to help distinguish NAT from AT. The study has associated small fracture ratios (≈1.6) with NAT and large ratios (≈2.8) with AT.[2] Another study using an immature canine model indicates that the fracture ratio is increased for a high rate of bone twist.[3] The authors of that study assume AT occurs at a high rate of twist while NAT occurs at a low rate; however, it is currently unclear if age is a covariate of the facture ratio generated under a torsional load.

The purpose of this presentation is to: (1) present new data on torsional fracture ratios using an immature porcine model; (2) examine the effect of age on the fracture ratio; and, (3) examine the effect of age on the rate of twist sensitivity in fracture ratio.

Thirty-six immature porcine femurs aged 1-17 days were twisted to failure in a servo-hydraulic machine using a custom-built torsional loading fixture. Twenty-two specimens were twisted at a low rate ($3°s^{-1}$), among which 14 specimens were from a young age group (1-9 days) while 8 specimens were from an older group (10-17 days). These age groups were previously defined by Powell et al.[4] Fourteen additional specimens from the young age group were twisted to failure at a high rate ($90°s^{-1}$). All specimens were frozen at -20°C within 12 hours of natural death. Specimens were thawed at room temperature and tested within 48 hours. The bones were kept moist with saline solution during all preparations and experimentation. The bone ends were potted in cups with room-curing dental cement. Specimen lengths were maintained at 3.10 ± 0.44 times the smallest diameter of each bone, as measured with calipers. The fracture ratio was determined post-failure.

The study demonstrated that for bone specimens from the young group, the fracture ratio increased linearly with age for both the high and low rates of twist. For the older group of specimens twisted at a low rate, there was no significant effect of specimen age on fracture ratio. For the young group of specimens, the fracture ratio generated in the high rate of twist experiments was consistently 1.3-1.4 times that generated in the low rate of twist experiments across all ages (1-9 days). An analysis of fracture surfaces showed alternating planes of transverse and longitudinal oriented fracture to be varied with age that directly related to changes in fracture ratio.

A previous study in the biomechanical literature suggests that the helical fracture pattern often characterized after torsional loading of a long bone is due to a combination of tensile and longitudinal shear failure.[5] It has also been shown that the tensile strength of bone typically increases with age and rate of loading.[6,7] Based on the previous biomechanical literature, the results of the current study suggest that the increase in fracture ratio documented with specimen age may be due primarily to an increase in tensile strength of the bone with age and rate of twist. Additional studies will be needed to support these hypothesized changes of tensile and longitudinal shear strength with specimen age for this long bone. A better understanding of these long bone fracture characteristics may be paramount as they may have significant implications in the interpretation of fracture ratio to be used in differentiating NAT from AT in children.

D4 Non-Destructive Test Method for Forensic Evaluation of Motorcycle Helmet Shell Failure Mechanism and Resulting Safety Deficiency Causing Fatal Head Injury

Kenneth J. Saczalski, PhD, 1440 W Bay Avenue, Newport Beach, CA 92661; Mark N. West, BS, Environmental Research & Safety Technologists, 1440 W Bay Avenue, Newport Beach, CA 92661; Todd Saczalski, BSMET, 140 Calle Irena, Sedona, AZ 86336; Joseph L. Burton, MD, 13784 Highway 9, Alpharetta, GA 30004; Paul Renfroe Lewis, Jr., MS, Bioforensic Consulting, 55 Park Square Court, Ste 207, Roswell, GA 30075; and Mark C. Pozzi, MS, Sandia Safety Sciences, 2 Marietta Court, Ste A, Edgewood, NM 87015*

After attending this presentation, attendees will understand how to apply a method for non-destructive analysis for scientific evaluation of potential manufacturing flaws in certified motorcycle helmet shell structural failures that result in severe head injury.

This presentation will impact the forensic science community by providing a non-destructive, evidence preserving method for evaluation of potential manufacturing defects in motorcycle helmet exterior shell failures associated with severe head injuries.

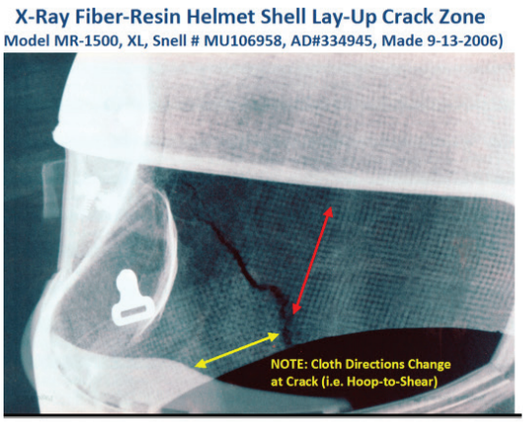
Concussion and severe head injuries sustained by motorcycle-helmeted riders using Snell and Department Of Transportation (DOT) -certified helmets are sometimes caused by manufacturing defects in the composites and plastic materials typically used in the fabrication of the critical outer protective helmet shells. The structural integrity of the outer shells is necessary to fully engage and spread the head/helmet outer surface contact impact forces over as large of a surface area and volume of the inner energy-absorbing liner as possible to minimize high-intensity focal impact forces that would otherwise transfer to localized regions of the skull/brain system and contribute to a more severe loading; however, if the shell integrity and containment load-distribution-function capability fails when the helmeted head strikes the pavement, such as when a sudden crack propagation failure in the shell occurs due to a manufacturing deficiency, the impact loads to the inner liner and head and are then concentrated on a smaller surface area, with concomitant higher focal impact that often results in severe-to-fatal load levels in the skull-brain system.

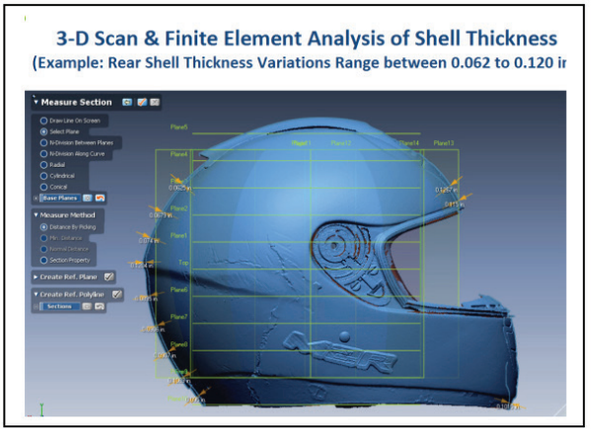
The two most common motorcycle helmet shell construction materials are the less expensive and easily fabricated injection molded thermoplastics shell, such as the polycarbonates types, and the more expensive fiber-resin laminate lay-up composite shells. Crack propagation failures in the polycarbonate helmet shell designs are typically caused by the formation of high-stress concentration impurity sites that result from mixing the more uniform and stronger virgin polycarbonate plastic material with older, used, reground plastic material obtained from the reuse of previously molded and rejected shells, which save on material-fabrication costs. With regard to the fiber-resin laminated composite shells, "resin-starved" laminates cause typical manufacturing flaws and shell stress concentration and load distribution failures. In addition, irregular laminate ply-lay-up and overlap coverage, coupled with large material thickness variations, also result in shell failure zones. The side-by-side figure below illustrates two fatal accident helmet cases in which shell fracture occurred and allowed localized loading to the skull-brain system. The left photo shows a fiber-resin composite shell failure and the right photo illustrates a polycarbonate molded shell failure.

Early research by Hodgson and Saczalski have addressed helmet performance and design issues related to the biomechanics of head-helmet loadings, and associated injury risk effects on humans, by using both analytical-numerical analysis methods and destructive impact testing of helmet systems and components; however, in order to preserve and maintain evidence in the "as-found" condition, which is needed for forensic reasons, a damaged motorcycle-accident helmet that exhibits crack failures in the outer shell structure requires the use of Non-Destructive Evaluation (NDE) techniques as well as dynamic-impact testing of exemplar helmets.[1,2] This study presents an NDE approach for identifying potential manufacturing flaws in motorcycle helmet shell structures made of both fiber-resin composites and plastic molded shells in which shell fractures resulted in severe head injuries.

The NDE method used in these helmet-failure studies involves three stages. First, the fracture sites on the outer and inner surface of the shells are carefully examined by using macro-photographic evaluation, both before any helmet disassembly is performed and after disassembly, in order to more carefully examine the damage zones of the crack region of the shell, as well as to examine the mating surface of the inner energy-absorbing liner materials. This stage of the examination documents "close-up" visual evidence of impurities in the plastic molded material shells and also reveals irregularities in fiber-resin fracture patterns in composite shell structures, often associated with "resin-starvation" or improper cure of the resin matrix chemical bonding. Second,

the helmet shell materials are examined for zones of flaws through the thickness of the material by using ultra-sound scans and X-rays to more carefully examine irregularities within the shell materials. Third, the accident shell structures are digitized with 3D scanning devices to enable accurate measurements of shell thickness variations at and around the regions of the shell fracture. Finally, if located, exemplar accident helmets are tested to evaluate several of the observed factors, including duplication of failures and consistencies of shell flaws as well as comparison with non-defective designs. The figure below illustrates an X-ray of the fiber-resin shell shown above and a "finite-element" thickness model.





The photo below shows the results from a drop-impact test run on an exemplar of the polycarbonate helmet shown on the right side in the first photo above. This test duplicated the accident helmet failure when tested according to the National Highway Traffic Safety Administration (NHTSA) helmet standard FMVSS-218. As noted above, the blending of recycled plastics with virgin materials in the molding of plastic helmet shells will likely lead to inclusions of impurities and stress concentration failure sites. The exemplar tested plastic and fiber-resin composite shell helmets allow for more detailed material defect testing in the forms of Differential Scanning Calorimetry (DSC) and Fourier Transform Infrared Spectroscopy (FTIR).

The NDE and exemplar helmet testing methodology applied in this study provides an efficient and economical means for verifying dangerous manufacturing defects in DOT- and Snell-certified helmet designs without the need for destructive testing on the actual accident helmet in evidence. Finally, it should be noted that evidence of a shell fracture does not necessarily verify a manufacturing defect unless a procedure such as that employed in this study is conducted.

Helmet Defects, Head Injury, NDE Evaluation

D5 Fire Dynamic Simulation — Assessing Structural Damage and Suppression Potential of a Church Fire

Darren Franck, MSME, Advanced Engineering Associates, Inc, 4713 MacCorkle Avenue, SE, Charleston, WV 25304; and Harold Franck, MSEE, Advanced Engineering Associates, Inc, 4713 MacCorkle Avenue, SE, Charleston, WV 25304*

After attending this presentation, attendees will better understand the use of fire dynamic simulations to determine the extent of structural damage and suppression potential during the progression of a fire.

This presentation will impact the forensic science community by demonstrating analytical tools to determine culpability in the protection of a historical structure.

This case study details an investigation of a fire at a historical church in Provo, UT. The church's construction dated to the 1880s and included much of the original framing. The attic contained a plywood deck that was installed in the 1980s, at which time smoke detectors were installed within this space. In late 2010, the church was holding an annual Christmas play. Alterations to the lighting system were made temporarily for the play. The changes included removal of the existing light fixtures in order to descend a decorative lighting truss through the ceiling. The contractor performing this work placed one of the fixtures on the plywood deck; however, he failed to turn off the light, which eventually led to a smoldering fire. Although some witnesses smelled smoke during the play, no one had been in the attic since the lighting system was placed in operation. Some time after the end of the play, burning embers breached the perimeter of the fixture and developed into a full-scale fire. This fire progressed through the attic and eventually consumed much of the roof, which led to a partial collapse of the structure.

The cause of the fire, while accidental, resulted in action against the lighting contractor; however, pertinent issues of suppression potential and a failure to recognize the fire were raised. The fire was not discovered until several hours after the end of the play. Past false alarms in the smoke detection system confused the security detail during the initial alarms. This confusion resulted in a 90-minute delay in responding to the fire, at which time the fire began to breach through the attic floor and into the ceiling of the church. In order to assist in a determination of the effects of this time delay on the condition of the structure and suppression potential, representatives with the church commissioned a fire dynamics simulation of this event.

The investigation began by reviewing the findings of the fire marshal, who was intimately involved in fighting the fire and in determining its cause. Modeling the fire required detailed knowledge of the dimensions of the church and materials used in the construction, especially within the attic. The shell of the structure was still in place at the time of the site visit; however, considerable efforts were underway to salvage the original brick walls and to expand the depth of the foundation. These efforts, as well as the extensive gutting of the church following the fire, limited the information available for use in the model. Information based on the as-built diagrams, plans devised during past remodeling, and the photographic record assisted in reconstructing the roof frame and the contents of the attic.

Fire Dynamic Simulation (FDS) and Smokeview software was used to perform the analysis. This software was developed by the National Institute of Standards (NIST) and has been widely used in both design of fire safety equipment and the reconstruction of fire events. FDS is a computational fluid dynamics model of fire-driven fluid flow. Smokeview is a visualization program for the results of the simulation. Input variables and output files are written into Fortran code and solved within the FDS program. Computing these results for a large-scale fire over a long period of time proved challenging for both the analysts and hardware.

Modeling the fire involved setting global boundaries, defining cell sizes, assigning materials (i.e., wood and metal) to the solid items within the attic, and setting the geometry for these items. Ventilation at the ridge and gable ends was also included in the model. In order to limit computational time to periods of days rather than weeks, the cell sizes were selected toward the maximum limit recommended by the program developers. The large cell sizes limited assessment of the progression of the fire within the interstitial spaces of the ceiling frame. Additionally, the program requires sloped and curved objects to be modeled in Cartesian coordinates, which creates vortices at the resultant corners that limited the ability to complete some simulations. This problem was alleviated by a modification to the software code; however, these changes limited the amount of information gleaned by the analysis.

The results of the analysis were consistent with the time frame developed by the original fire investigators. Output data included burning rates, gauge heat flux, soot mass fraction, as well as surface and air temperatures. Soot levels indicated that the smoke detectors would have been activated within a few minutes after the smoldering fire breached the perimeter of the light fixture shield. Testing performed by the fire marshal indicated that the smoldering fire would develop into open flames once air was introduced into the fuel mixture. The duration of this test is consistent with witness observations during the play and the timing of the smoke alarms. Thus, the delay in responding to the fire was no greater than 90 minutes.

Still, this represents a considerable time for open flames to spread throughout a large, open attic. The fact that the roof frame was composed of wood that had dried for more than a century in a desert environment likely increased the rate of consumption. The results of the analysis confirmed the decision by the fire chief to avoid entering the attic after the fire was ultimately discovered. The extent of damage to the framing members and temperatures within the attic precluded an interior attack. The limitation of the suppression efforts to a defensive approach prevented any successful salvaging of the structural elements. The actions of the security company were assessed, namely their failure to recognize the signs of a fire and respond to the alarms;

however, a few conditions that were out of the security company's control factored into these failures.

Fluid, Soot, Burning Rate

D6 Application of Reverse Engineering in Forensic Investigation

Wego Wang, SciD, 205 Bristol Road, Wellesley, MA 02481*

After attending this presentation, attendees will be able to: (1) apply appropriate reverse engineering methodology to their forensic analyses; (2) analyze the root cause and explain the circumstance of an accident by applying the principles of reverse engineering; and, (3) collect the relevant evidence as a subject expert witness in a forensic investigation based on reverse engineering practices.

This presentation will impact the forensic science community by assisting attendees to better understand the scientific methodology and engineering analysis in reverse engineering, their feasibility and applicability in forensic investigations, and the roles they have played in many recent successful cases. This presentation will discuss how to use everyday cameras and apply the principles of photogrammetry to create drawings and 3D models of objects pertinent to forensic investigations, such as the details of an involved crime site or building layout.

Most forensic investigations begin with the "apparent" end result, such as a burned-down house, collapsed bridge, damaged machinery, or wrecked vehicle. From this starting point, the forensic investigator collects data and gathers evidence to "reverse engineer" what has happened and how it happened. The application of reverse engineering to forensic investigation can help resolve the questions pertinent to who, what, where, when, why, and how from an engineering perspective in particular.

The availability of modern technologies in reverse engineering plays a pivotal role in many successful forensic investigations. This presentation will first briefly discuss the principles of reverse engineering, then focus on its applications in various real-life forensic investigations relative to transportation accidents, natural disasters, and personal injury. In these case studies, both the merits and limitations of reverse engineering will be discussed, as are the potential impacts of reverse engineering in future forensic investigations during the next decade.

Determination of the residual chemicals in fires caused by chemical explosions is essential. This presentation will discuss the advanced reverse engineering methods used for elemental material identification. For example, Inductive Coupled Plasma/ Optical Emission Spectroscopy (ICP/OES) is widely utilized for the determination of major component concentrations; however, it is subject to severe restrictions in the analysis of trace elements. For trace elements detection, glow discharge mass spectrometry is a more appropriate tool. On the other hand, for determination of included gases in a solid sample (e.g., carbon, sulfur, nitrogen, oxygen, and hydrogen) interstitial gas analysis is a more appropriate tool. This presentation will also discuss other readily available reverse engineering methods for chemical detection such as X-ray fluorescence analysis and techniques for analyzing coating materials.

During a forensic investigation, the photographer takes images from the 3D world and projects then onto a flat 2D image plane, but depth of information is lost. Photogrammetry reverse engineers this process. By knowing some information about the camera that took the photographs and by having a few more photos of the same object from a different perspective, some lost 3D information can be regained. The entire sets of 3D measurement data at accident or crime scenes could be captured by simply making the photos "photogrammetry friendly." A few skillful photos can make photogrammetric analysis easy.

Reverse Engineering, Forensic Investigastion, Chemical Analysis

D7 Evaluating the Structural Failure of Wood Bowstring Trusses Under Heavy Snow Loading

Daniel M. Honig, PE, Structures Consulting Engineers, PO Box 125, Swarthmore, PA 19081*

After attending this presentation, attendees will understand the factors which contributed to the cracking, structural failure, and/or partial collapse of several bowstring truss elements within a roof framing system, as well as the means and methods through which such a condition should be corrected to constitute safe occupancy of the building.

This presentation will impact the forensic science community by illustrating how uniform snow loads can negatively impact the structural integrity of roof framing members, particularly bowstring trusses, which are often subject to potential overstress under such conditions. This presentation also highlights the importance of thorough structural inspection and proper remediation methods, which can prevent buildings from experiencing complete structural failure of the roofing system.

During winter months, uniform or unbalanced roof snow loads can create stresses on the framing members of a roofing system; the weight of snow adds to the dead load of the system itself, supported by the members. This can lead to significant deflection and, over time, potential structural failure of these framing members. These conditions become more prone to occur as structural wood ages and experiences normal loading.

In this instance, the conditions experienced during the 2010/2011 winter season brought unusually cold temperatures for the Pennsylvania region, in addition to an increase in snowfall compared to preceding years. The unusual quantity of snow, in conjunction with lowered temperatures, led to the notable downward deflection and significant cracking in 6 of the 15 wood bowstring truss roof supports. These conditions were not localized to any particular roof area, rather they were widespread throughout various locations in the structure, furthering the evidence that these problems were caused by excessive snow loading across the roofing surface.

To properly remediate the damage to the trusses, and ensure the structural stability and safe occupancy of the building, computer analysis was performed using Rapid Interactive Structural Analysis for Two-Dimensional Planar Structures (RISA-2D) in order to evaluate the effects of varying live or dead loading conditions on a typical bowstring truss. These analyses found that under certain loading conditions, the bottom chords and web members of the bowstring trusses would experience twice the design stress for uniform snow loads, which could result in fracture, splitting, and possible structural failure of the trusses. Additionally, the presence of skylights within the building's roofing system were found to not only add to the dead load supported by select local trusses, but increase potential snow loading as a result of surrounding snow drift accumulation.

A structural remediation plan was detailed to properly reinforce and repair the bowstring trusses as needed, and thereby prepare the members to adequately support any snow loading during the impending winter season. It was recommended that tension reinforcements be added along the bottom chord of all members, in addition to the installation of reinforcement members along the lengths of the diagonal web members, which were determined to be insufficiently sized. The truss conditions also required the installation or replacement of bridging and diagonal bracing. Plans for adequate temporary shoring to prevent more significant damage or structural failure were also outlined, given that the initially installed temporary shoring was structurally inadequate to provide the support needed to prevent the roof framing system from experiencing failure during the upcoming winter season.

Bowstring, Failure, Snow

D8 Comparison of Measurement Error Between 3D Laser Scanning, Total Station Survey, and Photogrammetry Using PhotoModeler®

Shannon Wilson, J2 Engineering, 5234 E Pine Avenue, Fresno, CA 93727; James E. Flynn, BS, J2 Engineering, Inc, 5234 E Pine Avenue, Fresno, CA 93727-2109; Stephen Harper, BS, J2 Engineering, 5234 E, Fresno, CA 93727; and Jace Priester, BS, Three Space Imaging, 4690 E Peralta Way, Fresno, CA 93703*

After attending this presentation, attendees will be able to assign a confidence level to the method of measurement chosen for their specific purpose.

This study will impact the forensic science community by providing expert witnesses with information regarding the potential levels of error when dimensioning an object using a 3D laser scanner, a total survey station, or PhotoModeler® photogrammetry software.

The devices and software used were a FARO® Focus^{3D} laser scanner with SCENE software, a Trimble® 5000 series total station survey system, and photogrammetry using PhotoModeler® 6 to analyze photos and take measurements. All three methods were compared to known dimensions as determined with a steel tape. Three separate measurements were taken at various points on a tool cabinet. The measurements were taken at the points located at the edge of the wooden top, along the back supporting column, and from a diagonal located along the face of the base (see photographs below).

The FARO® scanner was used at high and standard definitions. The settings at high definition were set to ¼ resolution, which is a point density of .221 inch spacing at 30 feet, and 6x quality, which measures the same point six times and averages the distance. The settings at standard definition were set to ¼ resolution, and 4x quality. Scanning at standard definition required only one-third of the time needed to complete a high-definition scan. Four scans were taken at each setting and were registered by using SCENE software. Each measurement was taken three times and averaged for comparison to the steel tape. The Trimble® total station survey system used direct reflection for point gathering. The points were downloaded and labeled in the Trimble® office application and exported as a .dxf file. The .dxf file was then opened in AutoCAD® and measurements were taken by measuring the 3D length between points. Photos of the cabinet were taken and imported into PhotoModeler®, which was used to construct a 3D model of the cabinet. Measurements between the indicated points were obtained using the PhotoModeler® measuring tool. To obtain the diagonal measurement, an additional line was drawn and measured.

Error was determined by determining the difference between the digital measurement and the steel tape measurement for each point. The calculated percent errors were averaged for comparison. The average percent error for the high definition scans, standard definition scans, total survey station, and PhotoModeler® measurements when compared to the steel tape are 0.18%, 0.27%, 0.38%, and 0.36%, respectively. The maximum percent error for the high definition scans, standard definition scans, total survey station, and PhotoModeler® measurements when compared to the steel tape were 0.22%, 0.33% 0.49%, and 0.63% respectively (see tables below).

D9 Natural Language Engineering for Multilingual Forensic Author Identification

Carole E. Chaski, PhD, ALIAS Technology, LLC, Institute for Linguistic Evidence, 25100 Trinity Drive, Georgetown, DE 19947; Nan Decker, PhD, ALIAS Technology LLC, 25100 Trinity Drive, Georgetown, DE 19947; Ali M. Alshehri, MA, University of Buffalo, Dept of Linguistics, Buffalo, NY 14260; Seung-Man Kang, PhD, Chungbuk National University, International Services Center, Cheongju, SOUTH KOREA; and Angela Almela, PhD, Universidad Catolica de Murcia, Campus de Los Jerónimos, 135, 30107 Guadalupe, Murcia, SPAIN*

After attending this presentation, attendees will be aware of the challenges and opportunities for English, Arabic, Korean, and Spanish forensic linguistics, including natural language engineering toolkits that are being developed for specific forensic linguistic tasks.

This presentation will impact the forensic science community by demonstrating that forensic linguistic tools are becoming available for English, Arabic, Korean, and Spanish, which can aid in both international and national investigations.

The role of Natural Language Engineering (NLE) is increasingly recognized as necessary in forensic linguistics. The most successful approaches to authorship identification of small texts are based on syntactic patterns. Generally, the texts are tagged and parsed by parsers — a fundamental tool in NLE — with the subsequent syntactic patterns categorized, counted, and the output analyzed statistically.[1-6] The NLE approach faces two challenges that must be overcome for accurate forensic author identification: messy data and multilingual data.

First, most taggers and parsers have been built on edited text, such as novels or news writing, which abide by predictable orthography and syntax. But most forensic linguistic texts are unedited. Texts of unedited language are full of ungrammaticality, non-standard spelling, and variable punctuation. Such naturalistic texts are very difficult for part-of-speech taggers and parsers. The problem of parsing ill-formed input or ungrammatical sentences was first discussed more than 30 years ago, and it remains an incompletely solved problem.[7-12] The difficulty of tagging and parsing ill-formed data has important consequences within the forensic context. In the forensic application, any error during a procedure can introduce reasonable doubt that the entire procedure's result is flawed. Therefore, forensic author Identification (ID) methods that rely on parsing using standard parsers without any concern for how well or poorly the parser handles ill-formed input may not be as accurate as reported since the parses upon which subsequent analysis relies cannot be trusted as accurate.[13] Even clean data from legal argumentation cannot be perfectly tagged/parsed by commercial tagging systems; in a recent test of nearly 100,000 words from legal publications, nearly 6,000 words (or 16%) required correction of the tags. Therefore, if the forensic linguistic method handles the data processing either through manual error checking or automatic error assessment, then the total procedure of automated authorship ID safely handles the ill-formed input of truly natural language typical of forensic linguistic data.

Second, most taggers and parsers have been built for English, with other world languages having fewer tools available for NLE. Most of the work in forensic linguistics has been concentrated in the English language, but this Anglocentric focus is untenable in the current geopolitical climate.[14-16] Thus, work has begun on developing a multilingual foundation for forensic linguistics using NLE.[17] This presentation reports on a series of experiments that test the accuracy of multilingual parsers on messy data in English, Arabic, Spanish, and Korean. Data was gathered from: (1) the internet using blogs and social media; and, (2) experimental protocols using known subjects who are native speakers of English, Arabic, Spanish, and Korean.[18] The documents are run through taggers in the Text Analysis Toolkit Toward Linguistic Evidence Research (TATTLER) system. Linguists with graduate degrees manually check the tags, correcting any that are erroneous. TATTLER automatically calculates the errors per sentence, document, and language data.

After attending this presentation, attendees will better understand the distribution of citrate along porcine rib bones as well as variance between individuals.

This presentation will impact the forensic science community by providing results for an area of research that is lacking in literature. This presentation will add to research previously performed to evaluate the potential of citrate concentration as a means to estimate postmortem intervals by broadening the understanding of the distribution of citrate within porcine rib bone samples to better determine sampling requirements for the use of this method in forensic investigations. Furthermore, this presentation will provide and outline the methods needed to evaluate citrate concentrations using High-Performance Liquid Chromatography (HPLC).

Estimation of the Postmortem Interval (PMI) can be critical in cases involving decomposed human remains. Current techniques of PMI estimation are based on soft tissue decomposition, but these techniques are generally useful only in the active stages of decomposition. Alternative methods using skeletal remains have been investigated as a means to circumvent the limitations of soft tissue decomposition techniques. One of the most promising and recent techniques of PMI estimation of skeletal remains has sought to utilize the degradation of citrate within bone, which accounts for nearly 80%-90% of all citrate in the body.[1-5] The earliest studies using this method suggested the ability to use citrate content of bone to estimate PMI of up to approximately 100 years with a 1% error in the PMI determination.[5] Subsequent studies used the citrate method to compare estimated PMIs with known values to evaluate the success of this technique. Overall, it was determined that the method did not provide consistent results. An analysis of these studies demonstrated the need for a better technique for determining citrate concentrations and the need for a better understanding of citrate distribution within bone, as well as citrate variations among bones from different individuals.

In this experiment, two fresh racks of porcine ribs were acquired and subsequently frozen until use. The length of each rib was measured and subsequently divided into three equal-length sections based on the total length of the bone. The midpoints of each of the three sections (dorsal, ventral, and central) were identified and marked on the bone. Sections of bone were then cut to obtain one 2mm-4mm bone specimen. Immediately after sectioning, each specimen was processed through a bone-processing protocol and prepared for HPLC analysis. Citrate concentrations, in wt% from the cortical bone in each of the specimens, were recorded and compared to gain an understanding of the citrate distribution along individual bones, as well as the citrate variation across individuals.

A preliminary study using the method described above has suggested varying citrate concentrations in different portions of bone. Initial statistical testing has indicated a significant ($p<0.05$) difference between the ventral and dorsal areas of the bone. These preliminary results examined variations in a single individual; however, additional analyses are needed to determine whether the difference presently observed is consistent across individuals. Further analysis will determine how age and other factors influence citrate concentration in different bones and portions of bone.

In conclusion, this study seeks to provide a better understanding of citrate variation along bone to better evaluate the potential of a citrate-based method for determining the PMI. Early data has suggested that a large variation in citrate concentrations can be found depending on the location of sampling. Moving forward, this research seeks to gain more confidence through testing of different individuals. Overall, this study should help to provide more information on potential errors associated with the use of a citrate-based method for PMI estimation.

Postmortem Interval, Citrate, HPLC

D11 Crime Scene Imaging Using a Highly Affordable, User-Friendly, Portable, Open-Source 3D Imaging System

Nikolaj Kjaer Nielsen, Aarhus Univerisity Dept of Engineering, Skovbakkevej 21 lej 18, Brabrand 8220, DENMARK; Kim Juul Henriksen, BS, Aarhus School of Engieneering, Finlandsgade 22, Aarhus N 8200, DENMARK; Samuel Alber Trysoee, PhD, Aarhus School of Engineering, Finlandsgade 22, Aarhus N 8200, DENMARK; Henrik Pedersen, PhD, Dept of Engineering, Aarhus University, Finlandsgade 22, Aarhus N 8200, DENMARK; and Iana Lesnikova, MD, PhD, Havkaertoften 14, Tilst 8381, DENMARK*

After attending this presentation, attendees will be familiar with a highly affordable, open-source, fast-acting, portable imaging system able to perform a 3D scan of the body and surrounding areas during the crime scene investigation. The output is a colorized, dimensionally stable, and interactive 3D image, with a resolution of less than $1in^3$, thereby allowing clear visualization of small items, such as cigarettes or pencils.

This presentation will impact the forensic science community by creating awareness of new approaches in crime scene imaging. 3D crime scene imaging is thought to be a promising supplement to 2D photography or video and thereby provide an additional source of evidence. The method takes advantage of the modern 3D imaging technique, allowing rapid, accurate, and dimensionally stable 3D snapshots of the crime scenes. The presented solution is license free, independent of network or cell phone connection, comparatively inexpensive, and portable.

The examination of homicide scenes and other suspicious or obscure cases of death prior to body removal is an important part of the forensic pathologist's work. At the scene of death, the forensic pathologist records the body position, local environment, clothing, relation of the body to nearby objects, and condition of the body. According to current trends, forensic pathologists rarely tend to be involved in crime scene investigations, and thus important information that can only be acquired at the crime scene may be lost. Therefore, good documentation of the crime scene area will increase the quality of the forensic examination and provide more powerful conclusions. 3D imaging is believed to be a promising tool to positively expand this documentation.

The proposed method uses existing mass-produced technologies targeted at the gaming and entertainment industry. By using these technologies, it is possible to reduce the cost of a 3D scanning system by an order of magnitude. Generally, the concept is based upon projected, infrared, optical-scanning category, 3D mapping equipment produced for gaming systems. This specific type of technology has been used in many research projects regarding motion, gesture tracking, 3D mapping, and volumetric reconstructions. Therefore, this category of equipment has a fairly extensive documentation and provides a good research base, especially within compatible software and open software libraries for full utilization of the hardware capabilities.

To gather and process image information, an open-source software platform was developed. It constructs the 3D image and presents it in a manner which requires a minimum of time and technical knowledge. Figure 1 illustrates the visual results of the system, in its early development stages.

Figure 1: 3D model of a living test subject

The system is constructed in a portable manner by utilizing off-the-shelf hardware and open-source software in such a manner that construction of the system can be accomplished by a person with a normal understanding of the technology.

The study and development of the system was conducted in cooperation with the Institute of Forensic Medicine, University of Aarhus, and was tested in real-life scenarios.

Forensic Imaging, 3D Scanning, Open Source

D12 Is the Gatekeeper Concept Failing the Justice System? Is There a Viable Alternative?

John Nixon, CEng, MBA, ARC, PO Box 66, Bippus, IN 46713*

After attending this presentation, attendees will better appreciate what can go wrong when poorly vetted experts are ineffectively challenged by opposing attorneys, and then slip by judicial gatekeepers who may be unable to detect their flaws and are unwilling to reject them as witnesses. Options for improvement will be discussed.

This presentation will impact the forensic science community by alerting them to the inadequacy of current expert vetting procedures with particular regard to the role of the judge as gatekeeper. The forensic science community will be motivated to consider alternatives to the current system.

The featured case study focuses on a criminal murder case — an ongoing case that has been litigated for 21 years, during which time the defendant has been convicted of murder in two trials. Thirteen years into the litigation, prosecutors unveiled a new expert following revelations that one of their original experts had provided critical trial testimony that was diametrically opposed to information recorded in his previously undisclosed bench notes. Additionally, the original expert, with 37 years on the job, did not have the two degrees that were claimed on his curriculum vitae, and an academic transcript that he had provided was a forgery. The new expert subsequently gave some questionable testimony in a post-conviction hearing for a new trial, and appeared to be trying to justify the work of the discredited expert rather than embarking on an independent fact-finding quest.

In this case, several judges and several teams of attorneys failed to notice that an affable and confident expert was, in fact, a dishonest charlatan. That expert had testified in thousands of trials over the course of his 37-year career so, presumably, hundreds of judges and attorneys had failed to recognize him for what he was. A modicum of background research by any of the countless attorneys and judges who had allowed this witness to testify would have ended the charade. So why did not one of them do it in all that time? Or did they try and fail?

The case raises a number of issues relating to the prevailing system of having judges act as 'gatekeepers' with regard to expert qualification and testimony. Is it unrealistic for judges to rely solely upon the due diligence of opposing attorneys to provide evidence to dispute the integrity and expertise of a proposed witness? Are opposing attorneys capable of exposing bogus experts?

In a world of rapidly expanding scientific disciplines, perhaps using the courts as gatekeepers can be marginal at best and disastrous at worst. Is there a better way to ensure reliable, competent, and honest expert testimony? Should it be left to the diligence of legal teams to vet opposing experts thoroughly and engage their own expert to present an opposing view — thereby allowing the jury to weigh credibility? Perhaps the court would be well served by a third independent expert to provide expert analysis of the work of the experts of both sides — but do such independent experts exist, and how could their independence be assured?

Expert Verification, Expert Testimony, Gatekeeper

D13 The Federal Bureau of Investigation's (FBI's) Misrepresentation of Hair Evidence: History, Response, and Remedy

Peter D. Barnett, BS, Forensic Analytical Sciences, 3777 Depot Road, Ste 403, Hayward, CA 94545*

After attending this presentation, attendees will understand a brief history of the problems with the use of hair as a means of personal identification. The FBI's response to a determination that such evidence has been misrepresented in court by FBI examiners and a possible solution to such misrepresentation of evidence generally will be proposed.

This presentation will impact the forensic science community by explaining how unreliable scientific evidence is introduced at trial and how methods to prevent such introductions can be devised. Frequently, the problem lies in the content of the testimony, not the underlying science. Restricting expert witness testimony to the opinions and conclusions stated in a written report prepared for review prior to the trial could prevent such "blind siding" testimony at trial.

Hair is a potentially valuable form of evidence: It is universally present in essentially all mammalian species. Shed hairs are physically robust and not easily degraded. Casual observation reveals a great deal of variation of hair from one individual to another. Hair is a complex material with a great variation in the characteristics of features that can be discerned by a microscopic examination. Forensic scientists hoped to exploit the complex variability of these characteristics to determine that a hair recovered from a crime scene was from a particular individual. They recognized, and stated in reports, that human hair is not an absolute means for human identification, or words to that effect.[1]

With the advent of the ability to obtain genetic information from analysis of hair samples, it became apparent that there were instances in which a hair associated with a particular individual was not actually from that individual. As cases involving hair evidence were reviewed by various post-conviction organizations such as the Innocence Project, it was found not only that many reported hair associations were wrong, but the testimony presented to the juries vastly overstated the value of the evidence.[2] Misrepresentation of the value of hair evidence, by the FBI laboratory examiners and by other hair examiners, at least some of whom had been trained in the FBI laboratories, continued for 20 years.[3]

Potential problems in the FBI examination of hair evidence were described in 1981.[4] When testimony of FBI hair examiners came to the attention of the criminalistics community, it was widely agreed that such testimony had no basis in fact and was severely misleading. Finally, in 2015, following a growing recognition of errors in the association of a hair with a particular individual, and the frequent gross representation of the value of hair evidence by FBI examiners, the FBI instituted an investigation by the Inspector General.[5]

The reasons that FBI, and other, examiners reached and expressed such erroneous conclusions are many and varied. That this evidence and accompanying testimony came to be presented in so many trials underscores the ineffectiveness of the legal system to deal with scientifically false or unreliable expert testimony.

Attempts to ensure that scientifically reliable testimony is presented in trials have relied mostly on the ability of judges to determine that the basic technology involved is scientifically valid.[6] The admission of wrong, deceptive, or misleading opinions about hair evidence proves the deficiency in this approach. The problem is generally not the underlying technology; it is rather the overreaching expert testimony, aided and abetted by aggressive advocates. The courts explicitly permit this type of testimony.[7] Often, the testimony is unanticipated by opposing counsel and therefore goes to the jury relatively unchallenged. The oversight of judges in this context is ineffective.

Judges may not be able to evaluate the validity of the science behind the opinion offered by a scientist but may be able to determine whether the opinions and conclusions expressed by a scientist in an oral presentation are the same as the opinions and conclusions expressed by that scientist in a written report prepared in advance of the trial and made available for review by other scientists.

Lawyers facing the use of scientific evidence in court should have the ability, responsibility, and funding to obtain the assistance of knowledgeable scientists to review the work of scientists retained by other parties. All scientific evidence in a case should be reported in scientifically acceptable, written reports. Reports should be prepared in a time and manner to allow other scientists to review and respond to those reports. Reports should be available to the jury and judges. Oral testimony from scientific witnesses, if allowed, should be strictly limited to those opinions and conclusions expressed explicitly in the report prepared by the scientist.

D14 Quantification of Forces Generated by Volunteers in Stabbing Trials

Gary Nolan, BS, East Midlands Forensic Patholo, Level 3, Robert Kilpatrick Cli, Leicester Royal Infirmary, Leicester LE1 7LX, UNITED KINGDOM; Sarah V. Hainsworth, PhD, University of Leicester, Dept of Engineering, Leicester LE1 7RH, UNITED KINGDOM; and Guy N. Rutty, MD, University of Leicester, Forensic Pathology Unit, Robert Kilpatrick Bldg, Leicester LE2 7LX, UNITED KINGDOM*

After attending this presentation, attendees will understand the different levels of force that can be generated by volunteers stabbing a dynamometer. Attendees will appreciate the differing levels of force generated by men and women and will understand how these stabbing forces relate to the force necessary to penetrate the skin.

This presentation will impact the forensic science community by showing how engineering measurements of force can be used by forensic pathologists to help interpret the levels of force required in stabbing attacks.

Stabbing is the most common way of committing murder in the United Kingdom. The Crime Survey for England and Wales released in July 2015 revealed that the police recorded 26,370 offenses involving a knife or sharp instrument, which was a 2% increase for the year ending March 2015 over the previous year. Most of the increase was in the category of "assault with injury and assault with intent to cause serious harm," which was up 13%, but this was partially offset by a 14% decrease in robbery offenses using knives or sharp weapons. Knives and sharp weapons are therefore a major crime problem in the United Kingdom and other countries where guns are not readily available.

Some of the key forensic questions that are relevant to stabbing are how much force is required to create a particular stab wound and, in particular, how much force does a person stabbing with a particular instrument generate and how does this relate to everyday actions that can be communicated to juries.

In order to address these questions, this presentation reports on the development of a dynamometer for the measurement of force during stabbing with various implements into pork skin (a human skin analogue) or a skin simulant system. The dynamometer consists of two aluminum plates that are instrumented by force cells. The peak force generated by male and female volunteers was recorded for a range of scenarios using different implements and with different stabbing methods.

To analyze the data collected from the dynamometer, mixed effects linear regression was used. Since the experiment involved collecting multiple independent and continuous variables, mixed effects linear regression allows statistical analyses to be performed to understand whether the different variables had a statistically significant influence on the recorded results. Mixed effects models allow the use of both fixed and random effects in which the variables are inter-dependent rather than independent. This means that simple linear regression methods are inappropriate.

The results of these investigations demonstrated that men typically generate twice as much force as women when stabbing and that in the majority of cases, people generate higher forces with their dominant hand. The force generated in stabbing events is much greater than that required for penetration by a knife and, in almost all cases, volunteers were able to stab and penetrate both pork and the skin simulant system with a small amount of force.

In conclusion, the key issue in deciding whether a weapon creates a sharp force injury (stab wound) during a stabbing attack is whether the threshold force for penetration with that particular implement is met; therefore, it is critical to understand whether or not the tip of the weapon permits penetration. If the weapon penetration force is less than the force generated by stabbing, the victim's skin and underlying fat and muscle will always be penetrated.

Figure 1: A volunteer performing a stab into the dynamometer. Force data is taken from three load cells and the system was calibrated with known applied forces to ensure the peak forces that were recorded were accurate.

Stab, Force, Penetration

D15 Identification of Building Insulation and Soundproofing Products by Light and Electron Microscopy

Richard S. Brown, MS, MVA Scientific Consultants, 3300 Breckinridge Boulevard, Ste 400, Duluth, GA 30096-893*

After attending this presentation, attendees will better understand how Polarized Light Microscopy (PLM), Scanning Electron Microscopy/Energy Dispersive X-ray Spectrometry (SEM/EDS), and Analytical Electron Microscopy (AEM) were used to determine the composition of insulating and soundproofing materials.

This presentation will impact the forensic science community by providing an analysis procedure that was developed over several years and used to determine the composition of insulating and soundproofing materials so they could be compared to the manufacturers' formulas for the purpose of cost-recovery litigation to reimburse the building owner for the cost of abatement.

When the Environmental Protection Agency (EPA) was tasked in the late 1980s with the implementation regarding the inspection of schools for Asbestos-Containing Materials (ACM) and the decision to remove materials that were friable, litigation resulted in the acquisition of formulas used by companies identified as producing ACM. The analysis methodology developed, once the formulas were decoded and the array of terminology used for raw materials by different companies was understood, required the microscopical characterization of the ingredients utilizing PLM, SEM/EDS, and AEM (Transmission Electron Microscopy/Energy Dispersive X-Ray Spectrometry (TEM/EDS) with selected area diffraction) on each sample.[1] By analyzing the sample using this combination of microscopical techniques, a cross-check was provided during the analysis ensuring that all of the ingredients were accurately characterized. For example, if PLM detected gypsum, vermiculite, and montmorillonite clay, then SEM/EDS and AEM would be expected to find the same ingredients. Other analytical techniques such as X-Ray Diffraction (XRD), Gas Chromatography (GC), loss on ignition, and acid-soluble weight percents were employed when the sample matrix required additional work.

Once a building survey was completed, samples were examined for the presence of asbestos using the regulatory definitions of the fibrous asbestos minerals amosite, chrysotile, tremolite, actinolite, anthophyllite, and crocidolite. Samples were then submitted to the laboratory to determine the composition of the material for comparison to formulas provided by the courts. Samples were photographed "as received" to document number and layer sequence. Multi-layered samples were treated as multiple samples requiring a complete analysis of each layer. PLM analysis was performed using slide mounts prepared to obtain visual estimates of the materials comprising each sample. Sub-samples were obtained and distributed for acid-soluble weight percent, SEM/EDS, and AEM analysis. Samples containing low amounts of acid-insoluble materials required the reanalysis of the acid-insoluble material collected on the filter during the acid digestion procedure using 10% v/v hydrochloric acid. Mineral wools could be removed from most samples by heating the 10% HCl solution and dissolving the mineral wool.

Although the types of asbestos fibers present were important, the materials were sorted based on their major, minor, and trace components. Many products could be differentiated based on their determined composition when compared to the formulas provided. Some products were very similar among manufacturers and could not be differentiated by microscopical techniques alone. Major components such as gypsum, Portland cement, glass fibers (including mineral wools), clays, and diatoms (including synthetic materials produced from diatoms) were identified using the combination of microscopical techniques described.[2,3] AEM was especially useful for the asbestos identification, clay identification, and other crystalline minerals used in the various formulations.

Microscopy, Dust, Insulation

D16 Forensic Microscopy in a Case of Asbestos-Containing Cigarettes

James Millette, PhD, Millette Technical Consultants, 220 Cricket Walk, SW, Lilburn, GA 30047*

After attending this presentation, attendees will better understand how microscopy can be used to study evidence in an unusual civil asbestos case involving vintage (more than 50 years old) cigarettes made with filters containing crocidolite asbestos (Micronite® filter Kent® cigarettes).

This presentation will impact the forensic science community by providing information about handling and analyzing vintage samples to confirm their composition and to determine whether exposures to asbestos could have occurred in the 1950s when the Micronite® filter Kent® cigarettes were commercially available.

During the period of approximately March 1952 through May 1956, the Micronite® filter in Kent® cigarettes used crocidolite asbestos as part of the filtering agent. There was no barrier or secondary filter between the end of this filter and the customer's mouth. It has been estimated that approximately 585 million packs (more than 11 billion cigarettes) were sold in the United States using this design with advertising that emphasized the "health protection" supposedly provided by the filter.

Several packages of the 1952-1956 vintage Kent® cigarettes were obtained in their original sealed packaging and analyzed by Polarized Light Microscopy (PLM), Scanning Electron Microscopy (SEM), and Fourier Transform Infrared microspectrophotometry (micro-FTIR). The outer paper wrapper on the filter consisted of a white paper layer and a tan coating layer. The white paper was part of the continuous white paper that covered the entire cigarette. The inside of the filter consisted of rolled crepe paper with loose fibrous material. Some carbonate particles were also present. Both the white paper and the crepe paper were consistent with chemically processed wood paper fiber. The loose fibrous material consisted of crocidolite, cotton, and cellulose acetate fibers. The composition of the filter in terms of approximate percent by weight of total filter were: outer paper (white paper and tan coating), 16%; crepe paper including carbonate, 62%; crocidolite asbestos, 6%; synthetic fibers (cellulose acetate), 4%; and cotton fibers,12%. A corporate document described the Micronite® filter as containing cotton, crepe paper, cellulose acetate fibers, and approximately 7% to 25% crocidolite asbestos.[1]

The samples were examined for evidence of deterioration. No signs of mold, insect attack, or other deterioration were found. The crepe paper was found to be very flexible and had not become brittle with age.

Arrangements were made to test for particle release from regular and king-size Micronite® filter Kent® cigarettes using a standard smoking machine following generally accepted International Organization for Standardization (ISO) and Canadian smoke testing protocols.[2,3] A non-asbestos Kent® cigarette (later vintage) was smoked as a control. The smoke was collected on glass fiber Cambridge® filters. The filters were prepared for Transmission Electron Microscopy (TEM) using an acid/base digestion of the glass filter fiber that does not affect amphibole crocidolite fibers.[4] The samples were analyzed using American Society for Testing and Materials (ASTM) Standard Method D6281 for asbestos.[5] Crocidolite asbestos fibers were found to be released in the smoke of both regular and king-size Kent® Micronite® filter cigarettes.

Microscopy, Kent® Cigarettes, Asbestos

D17 The Potential of Comprehensive Gas Chromatography (GC) in Forensic Fire Investigations

Martin Lopatka, MSc, Science Park, Amsterdam, CANADA; Gabriel Vivó-Truyols, Science Park, Amsterdam, SPAIN; Marjan J. Sjerps, Laan van Ypenburg 6, The Hague 2497GB, NETHERLANDS; Peter J. Schoenmakers, Science Park, Amsterdam, NETHERLANDS; Arian C. van Asten, PhD, Netherlands Forensic Institute, Laan van Ypenburg 6, The Hague, Zuid Holland 2497GB, NETHERLANDS; and Andjoe A.S. Sampat, MSc, Science Park, Amsterdam, NETHERLANDS*

After attending this presentation, attendees will have insight into the potential use of comprehensive chromatography for forensic applications as well as its limitations. Attendees will be able to assess whether comprehensive 2D GC (GCxGC) and comprehensive GCxGC/Mass Spectrometry (MS) will meet their case work needs and make a valuable contribution to their forensic laboratory.

This presentation will impact the forensic science community by illustrating how detailed chemical information as revealed by comprehensive chromatography can lead to new dimensions in chemical analysis of forensic evidence.

The COMprehensive FORensics (COMFOR) project is a collaborative effort between the University of Amsterdam and the Netherlands Forensic Institute to develop forensic methods based on comprehensive GCxGC and GCxGC/MS. Comprehensive chromatography has been successfully applied in many areas, including the petrochemical and food industry; however, its potential has not been fully exploited in forensic science. The multidimensional separation principle and modulation process lead to enhanced separation power, peak capacity, and sensitivity. This creates new opportunities when performing targeted trace compound analysis, broad untargeted screening, class characterization, and chemical comparison of complex samples of forensic interest.

Chemical analysis in forensic fire investigations deals with complex and highly variable fire debris samples in which the presence of minor residues of ignitable liquids may be indicative of arson. As ignitable liquids are often oil distillates of complex composition, the use of GCxGC and GCxGC/MS is especially promising in the field of forensic fire investigations. In this presentation, the latest results of the COMFOR project will be presented. This includes a detailed study into the chemical variation of white spirits in the Dutch market as analyzed by GCxGC and GCxGC/MS. Despite the very complex chemical composition, production and distribution conditions are such that chemical variation at a given point in time is actually quite limited for different white spirit brands; however, within-class differentiation is still feasible through detailed comprehensive analysis in combination with data processing and chemometric tools. Additionally, small-scale fire experiments were developed and conducted to efficiently generate realistic fire debris samples under controlled conditions. Fire debris head space was sampled on carbon traps which were extracted with DCM. The DCM extracts were subsequently analyzed with GCxGC and GCxGC/MS to detect ignitable liquid residues.

Current research focuses on the use of comprehensive chromatography in combination with chemometric methods and forensic statistical data analysis to classify ignitable liquid residues with greater objectivity. Finally, this project explores the possibly of within-class differentiation of ignitable liquids in fire debris samples. The COMFOR research shows the benefit of chemists, chemometricians, and forensic statisticians working together to ensure state-of-the-art chemical techniques to be applied in forensic practice and resulting in an assessment of evidential value.

The COMFOR project is funded by the Netherlands Organization for Scientific Research (NWO) by a grant.

Forensic, Fire, Investigation

D18 Physical Evidence Used in Rollover Crash Reconstruction

Kurt D. Weiss, MS, Automotive Safety Research, 5350 Hollister Avenue, Ste D, Santa Barbara, CA 93111-2326*

After attending this presentation, attendees will be able to catalog and illustrate physical evidence on the vehicle exterior and roadway commonly used in the reconstruction of rollover crashes.

This presentation will impact the forensic science community by identifying artifacts that are often used in determining rollover crash parameters such as roll direction, rollover count, and vehicle orientation at ground impact; examples will be drawn from real-world collision investigations.

Collision reconstruction is the scientific process of investigating, analyzing, and drawing conclusions about the causes and events of a vehicle collision. Commonly occurring crash categories are head-on, rear-end, intersection, T-bone, sideswipe, and rollover. Each crash type creates a unique set of physical artifacts related to the pre- and post-impact vehicle dynamics. Investigation of these collisions requires techniques that draw upon the quantity and quality of the observed and documented physical evidence. The physical evidence commonly observed in rollover crashes is presented and discussed.

Physical evidence used in the investigation and reconstruction of rollover crashes can be placed into two categories: (1) roadway evidence; and, (2) vehicle evidence. Additionally, roadway evidence can be divided into two subsets: (1) pre-rollover evidence; and, (2) evidence deposited during the rollover event. Examination of the vehicle may reveal evidence to suggest a roll direction or rollover count, but combining these vehicle artifacts with those observed at the collision site will yield a reconstruction of increased accuracy.

Pre-Rollover Evidence: (1) tire friction marks identify a vehicle's heading and orientation on the roadway before it rolls over. These rubber deposits are created because the tires can no longer generate the required lateral force and the tires begin to slide; and, (2) furrows are much like tire friction marks in that they establish the vehicle's path prior to the rollover event, but they are on dirt or vegetation and not on a paved roadway. A sliding tire cuts into and begins to plow the soil, creating furrows.

Evidence of Vehicle's Rollover Trajectory: (1) the trip point identifies the location where the vehicle stops sliding and starts to roll over. Oftentimes, the trip point is at the end of the furrows or tire friction marks, but sometimes an object, such as a curb, can be the tripping mechanism; (2) gouge marks are created when the vehicle has impacted or slid on the roadway. Depending upon the part of the vehicle that contacts the pavement or soil, these gouge marks will have a unique set of characteristics; (3) wheel imprints on the roadway will have a crescent shape corresponding to the wheel rim curvature. The orientation of these imprints relative to the roll path direction in conjunction with knowing the rollover leading side will determine if they are left or right side wheels; (4) fractured glass is commonly observed along the vehicle's roll path because tempered glass will break under vehicle structural deformation or by interaction with objects such as rocks. Knowing the color (clear or tinted) and thickness of the glass can help establish the window-breaking sequence during the rollover event; (5) paint, plastic, and rubber transfers occur when the vehicle has translational velocity relative to the ground and, by virtue of this sliding mechanism, paint, plastic, or rubber of the component making contact is thereby transferred; (6) component debris field can be found along the rollover path and varies with regard to vehicle type and roll distance. This field can include side view mirrors, roof racks, trim, bumper fascias, hubcaps, and vehicle contents such as handbags, blankets, and clothing; and, (7) the point of rest marks the end of the rollover event. If the vehicle does not rest on its wheels, dimple-like impressions may be observed on the vehicle exterior.

Vehicle Exterior: (1) scrapes on the vehicle exterior are indicative of ground contact. The orientation of unique collections of scrapes provides evidence for the roll count. Long scrapes suggest higher translational velocity relative to the ground; (2) wheel assemblies can reveal scrapes, gouges, or fractures. The side of the vehicle where these wheels reside will aid in determining vehicle orientation leading to and throughout the rollover phase of the collision sequence; (3) material flow to plastic components occurs when these vehicle parts impact the ground. Along with abrasions, if contact is sustained, material temperature can increase resulting in material flow in a direction opposing the vehicle's roll direction; and, (4) vegetation can become trapped in the wheel rim-tire bead junction. Observation of this material can indicate whether the vehicle rollover occurred on or off the pavement.

Thorough examination of physical evidence observed on the vehicle exterior and roadway will assist the investigator in a more accurate collision reconstruction. Commonly observed physical evidence is presented.

Physical Evidence, Rollover Reconstruction, Vehicle Artifacts

D19 Biomedical Engineering Contributions in the Analysis of Head and Brain Impact With Legal Perspectives by Counsel for the Department of Transportation: Bicycle vs. Auto, Seatbelts, and Motorcycle Accidents

Laura L. Liptai, PhD, BioMedical Forensics HQ CA/FL, 1660 School Street, #103, Moraga, CA 94556; and Landa S. Low, JD*, California Department of Transportation, 111 Grand Avenue, Ste 11-100, Oakland, CA 94612*

After attending this presentation, attendees will have a better understanding of how biomedical engineering principles apply to the engineering analysis of head and brain impact injuries.

This presentation will impact the forensic science community by demonstrating the importance of biomedical engineering analysis of head and brain impacts.

In the forensic analysis of a head or brain impact incident, the biomedical engineer is uniquely situated to offer insights with respect to the quantification of forces and accelerations. Because of the multidisciplinary aspects of most head and brain injury incidents, the biomedical engineer is able to tie the engineering aspects together with the medical diagnoses by the health care providers and forensic pathologists. Various head impact scenarios are analyzed from an engineering perspective and supported with analysis of physical evidence and/or experimentally verified test data.

Experiments conducted follow Federal standards using data acquisition software at 10,000Hz with a 4th-order Butterworth filter with a 1,650Hz cutoff frequency, per the Society of Automotive Engineers (SAE) J211. These experiments used different impact surfaces, including asphalt, and vehicle sections. Impact speeds were determined and replicated using an inverted pendulum impact protocol. Anthropometric crash test dummy head-forms and necks were used to study the multi-axial direct contact to the respective impact surfaces in both helmeted and unhelmeted modes in which the anthropometric sections are instrumented with triaxial piezoelectric ICP® accelerometers.

The legal perspective is provided for three cases involving different mechanisms of injury: helmet, occupant restraint (seatbelts), and bicyclist head impact. Counter arguments are presented to provide a complete perspective of the litigation issues. Also presented will be how the issues changed prior to trial that, in one case, changed the course of the trial itself.

The case studies for this presentation involve various allegations over the use (or non-use) of various mechanisms to prevent injury or death: seatbelts, motorcycle helmets, and bicycle helmets. The biomedical engineer's analysis sheds light on both liability and damages issues, presents the factors that caused the accident and the resulting injuries, and discusses whether the injury would be reduced or eliminated with the proper use of a restraint device or helmet.

The case background, forensic questions, and brief results are summarized below for each of the three cases to be discussed. The presentation will include discussion of the engineering approach, fundamental principles employed, methods, results, and conclusions.

Seatbelt Analysis: a woman and her husband pulled out to make a left turn onto a rural two-lane highway, directly into the path of a truck, resulting in a relatively low-speed impact. The husband in the passenger seat died as a result of a head/brain injury. Plaintiff argued that her husband was wearing a seat belt, but nonetheless suffered a fatal injury. The defense argued that he was not wearing a seatbelt and would likely have survived the accident if he had been wearing one. A careful analysis of the trauma clearly revealed the mechanism of injury resulting in this man's death. This case went to trial.

Solo Motorcycle Accident: a young woman was a passenger on a motorcycle when the rider, who was going uphill on a curve, struck a guardrail, ejecting his passenger. She struck something with her face, which caused massive facial trauma. Plaintiff alleged she hit a nail sticking out of the stop sign post. But, could it have been a guardrail post, the ground, or something else? Biomedical engineering analysis determined the mechanism of injury. The matter settled.

Bicycle vs. Auto Accident: an un-helmeted bicyclist was struck by a car as he crossed a freeway on-ramp. He was thrown over the car and struck his head on the asphalt, suffering a severe traumatic brain injury. Plaintiff argued that he was not astride his bicycle, but was riding it as a scooter, with his right foot on the left pedal. Because he was not technically "riding," he did not legally have to wear a helmet. Defense argued that the injuries would have been prevented or significantly lessened if he had been wearing a helmet. Careful biomedical engineering assessments pieced together the physical evidence, some of it missed by both the accident reconstruction and bicycle experts, to determine how the injury occurred. An experiment then quantified the accelerations with and without a helmet. The matter settled.

Biomechanics, Brain, Impact

D20 Non-Collision Moving Vehicle Fire Caused by Escape of Exhaust Heat and Combustion Gases Due to Muffler Design and Materials Defects

Mark C. Pozzi, MS, Sandia Safety Sciences, 2 Marietta Court, Ste A, Edgewood, NM 87015; Dean L. Jacobson, PhD, 4665 S Ash Avenue, Ste G4, Tempe, AZ 85282; David Bosch, PhD, 4665 S Ash Avenue, Ste G4, Tempe, AZ 85282; and Scott Anderson, BS, 4665 S Ash Avenue, Tempe, AZ 85282*

After attending this presentation, attendees will understand how a wide range of forensic investigation and analysis techniques, ranging from fire cause and origin to metallurgical analysis of materials and welding to analysis of how and why fire can spread rapidly, can be employed.

This presentation will impact the forensic science community by describing the methodology utilized to investigate a non-collision fire involving a moving vehicle which had demonstrated no known pre-fire operational defects or damage.

A two-door utility vehicle in original equipment manufacturer (stock) condition ignited and rapidly burned while being driven at normal highway speed on a paved road. There was no evidence of a collision, other pre-fire vehicle damage, or operational malfunction of seats or doors. Despite immediate rescue efforts by the initially uninjured driver, two conscious, initially uninjured children restrained in safety seats in the rear seat of the vehicle died due to the extremely rapid spread of the fire. Forensic examination of the vehicle showed a burn pattern consistent with a fire originating from the carpeted interior floor pan area between the front and rear seats. The fire then spread via burning of the adjacent front and rear seats. There was a corroded hole in the floor pan directly below the area of fire origination. Below the floor pan hole was the muffler, which showed clear evidence of long-term pre-fire deterioration, including a missing heat shield. This allowed exhaust gases to heat, corrode, and eventually penetrate the floor pan and the flammable interior components above the hole. The muffler utilized a combination of poor design, inferior construction techniques, and inferior materials that caused or contributed to the escape of hot, corrosive exhaust gases, as well as allowed those gases to strike the unprotected floor pan for an extended period of time. Because the hole in the floor pan was covered by carpeting and insulation, these defects were not noticeable to the operators of the vehicle prior to ignition.

Vehicle interior materials were apparently certified by the manufacturer to be in compliance with the flame resistance requirements of Federal Motor Vehicle Safety Standard (FMVSS) 302; however, these materials were not capable of handling the prolonged heating caused by the hot exhaust gases, particularly when applied to the underside of the padded carpeting. This is not a heat vector typically anticipated by FMVSS 302, but it is certainly foreseeable given the close proximity to hot exhaust components. Once ignition conditions were reached, the spread of the fire was extremely rapid. Despite immediate attempts to remove the two rear-seated occupants, they both perished in the fire.

There have been limited research studies on the effects of exhaust system heat, particularly that generated by catalytic converters or mufflers, causing fires related to flammable materials such as dry vegetation, dead leaves, and paper on the ground under parked or running vehicles; however, this case involves a type of exhaust system failure and adjacent vehicle structural/materials failure which is substantially different. The extremely rapid onset of fire illustrates that vehicle interior materials may be far more dangerous when subjected to some types of foreseeable ignition sources than were anticipated by FMVSS 302.

The extremely rapid spread of fire in the interior of a vehicle that was supposedly compliant to FMVSS 302 is also notable. Based on available information, this type of fire normally does not result in a loss of life, therefore it likely does not receive as much attention from automotive manufacturers or safety regulators as other types of vehicle fires. Emergency egress from a vehicle, particularly rear seated occupants, is a commonly overlooked aspect of passenger protection.

The educational objectives of this presentation will be relevant to forensic practitioners in the engineering sciences, fire and arson investigation, vehicle design, accident investigation, criminalistics, jurisprudence, and pathology, with potential interest to those in toxicology and general forensic sciences.

FMVSS302, Non-Collison, Fire

D21 Refueling Fire Caused by Defective Fuel Pump Nozzle, Electrostatic Discharge Ignition, and Violations of Safety Practices

Mark C. Pozzi, MS, Sandia Safety Sciences, 2 Marietta Court, Ste A, Edgewood, NM 87015*

After attending this presentation, attendees will be able to demonstrate how proper forensic investigation can determine, by using the scientific method, how to conclusively prove fire cause and origin, and how it relates to injury causation, property damage, violation of safety procedures, and related issues.

This presentation will impact the forensic science community by illustrating the methodology for investigating an emerging fire hazard, describing how to investigate a catastrophic refueling fire, and demonstrating how the source of fuel leakage and ignition was determined and how other sources of ignition were eliminated.

This presentation involves a forensic investigation of a gasoline refueling fire at a self-serve station. Multiple violations of safety practices before and during the fire caused or contributed to the fire. These violations caused a known defective fuel pump nozzle to remain in service with no warnings to consumers or lock-out/tag-out precautions. Documented failures of the nozzle earlier on the day of the incident were ignored by the operators of the refueling station. When utilized to fill a vehicle in the normal manner, the defective filler nozzle failed to shut off, spilling a large amount of gasoline from the filler neck onto the ground as the pump continued to operate. This falling fuel was capable of generating significant static electricity. No emergency shut-off switch was available near the gasoline pump. The vehicle passenger attempted to manually shut off the nozzle without success. The driver began to exit the vehicle to deal with the leaking fuel. When the driver rotated and slid off the seat and then touched the ground, an electrostatic discharge was generated sufficient to ignite the vapors spreading from the overflowing gasoline. A catastrophic fire resulted, which caused severe burns to the driver, destroyed the vehicle and refueling pump, and also destroyed much of the gas station. The station attendant failed to observe the refueling operation and failed to shut off the fuel pump even when aware of the fire. This caused the pump to continue to supply full-flow pressurized fuel to the fire for several minutes. Evidence of defects in the refueling nozzle were discovered; these defects caused the nozzle to malfunction, preventing proper shut-off. Claims that the fire had ignited because the driver had left the engine running were disproven via forensic inspection of the engine and components of the ignition system. There were no contributions to the fuel leak or fire by the vehicle or its occupants. Also, claims made that evidence spoliation had occurred as a result of the forensic investigation were disproven by the use of on-scene and subsequent photographs and other data. A previous similar incident at a different station operated by the same company was also uncovered, which had not been disclosed.

Refueling fires which were ignited by Electrostatic Discharge (ESD) ignition have been known for many decades. There have been approximately 200 reports of ESD ignition related to ground vehicle refueling fires in the United States since the late 1990s, with initial suspicion that cellular telephones were responsible; however, ESD was the actual cause. This has become a recognized significant hazard resulting in warnings being posted on many refueling pumps. ESD has caused fires in both ground vehicle and aircraft refueling, and it can occur with propane as well as liquid fuels.

Refueling, Defective, Electrostatic Discharge

D22 Friction Tire Testing of a Run-Flat Condition Sport Utility Vehicle (SUV) Tire

Kurt D. Weiss, MS, Automotive Safety Research, 5350 Hollister Avenue, Ste D, Santa Barbara, CA 93111-2326; and Jacqueline Paver, 501 Meigs Road, Santa Barbara, CA 93109*

After attending this presentation, attendees will better understand the value of dynamic tire friction testing as a tool for collecting data that relates tire inflation pressure to the rolling friction of a run-flat SUV tire.

This presentation will impact the forensic science community by providing data for speed calculations at the start and end of tire friction marks. This data will help traffic collision reconstructionists understand the effect of tire inflation (e.g., the run-flat condition of a rear tire) on vehicle (and occupant) kinematics and dynamics. These results are also important to biomechanical engineers, because the literature documents increased likelihood of vehicle instability and rollovers, and increased likelihood and severity of injury as a result of loss of tire pressure and/or failure.

Collision Overview: On a desert highway, the right rear tire of an SUV catastrophically failed at approximately 70mph. Pre-rollover tire pressure loss resulted in an unintended vehicle heading change. Right oversteering driver input resulted in clockwise yaw, but then left oversteering driver input resulted in counterclockwise yaw. Front tire friction marks were documented. The SUV traversed down a dirt and rock embankment. The SUV flipped, passenger-side leading, at about 40mph and rolled uphill 3¼ times over a distance of approximately 125ft. The SUV came to rest on its wheels.

The female driver sustained fatal head, chest, and abdominal injuries with extensive musculoskeletal fractures. The left second-row, ejected male passenger sustained diffuse axonal brain injury, neck fracture, and chest injuries with residual impairment. These injuries most likely occurred inside the vehicle or during ejection.

Tire Analysis: The subject vehicle and failed tire were inspected by tire experts who agreed with the sidewall failure mechanism (i.e., a complete circumferential separation of the outer sidewall from the tire casing due to operation while severely underinflated). A tear observed on the failed tire inner sidewall adjacent to the tread belt was hypothesized as the source of the air pressure loss. In this instance, it was unknown how long it took the tire to deflate and cause the outer sidewall failure.

Dynamic friction testing was conducted with an exemplar SUV equipped with a new 275/60R16 tire installed on the right rear wheel. Tests were performed on a rough and weathered asphalt roadway. The test vehicle was accelerated to a speed of 39mph to 53mph and then allowed to coast (i.e., without brake application) to speeds between 16mph and 22mph. The test matrix included two test runs each for both directions of the roadway. A baseline test of the vehicle's overall rolling friction (including air resistance) was determined with all tires inflated to 38psi. Then, the air pressure of the right rear tire was bled out to 20psi, 10psi, and about 3psi, respectively. The four test runs and resulting deceleration rates were averaged for each test tire pressure. Vehicle speed was measured at 20Hz with a Racelogic VBox II Lite.

The test tire was documented with: (1) an exterior-mounted video camera that captured the tire flex and road noise; and, (2) an on-board video camera that captured steering wheel and operator motion due to the low-pressure right rear tire.

Results: The test data was analyzed using the VBox Tools software. The overall road friction (including air resistance) of the test SUV was -0.0263g at 38psi and 20psi, -0.0325g at 10psi, and -0.0435g at about 3psi. Despite the rough and weathered test roadway asphalt, the steering wheel did not appear to demonstrate significant rotation or vibration as a result of the low pressure in the test tire; however, the noise level recorded by the external video camera, as well as that detected by the test vehicle operator, was remarkably loud inside the vehicle cabin. Surprisingly, the outer sidewall temperature of the test tire with about 3psi was too hot to touch immediately after testing. Test results demonstrated the value of dynamic friction tire testing and the results show that overall road friction increases with decreasing tire pressure.

Run-Flat, Friction, Rollover

D23 Witness Identification Under Low Light-Level Conditions: A Case Study

James B. Hyzer, PhD, Hyzer Research, 1 Parker Place, Ste 330, Janesville, WI 53545-4077*

After attending this presentation, attendees will be aware of a case study in which the defense in a capital murder case unsuccessfully argued that the defendant shooter was not able to identify his victim as a police officer under the low light-level conditions that they alleged existed at the scene of the crime.

This presentation will impact the forensic science community by increasing awareness regarding nighttime visibility, mesopic vision, photometry, illumination, and the pitfalls associated with trying to use photography as evidence to demonstrate to a jury what an individual could or could not see under low light-level conditions.

The subject case involves the shooting death of Officer Travis Murphy by defendant Danny Martinez in a Phoenix, AZ, residential neighborhood at approximately 1:30 a.m. on May 26, 2010. A defense argument was that the defendant did not know he was shooting a police officer because of the low light-level conditions that existed when he fired his shots. In his report, one of two visibility and illumination experts for the defense stated the following: "Therefore, based on my measurements and observations and with reasonable scientific certainty, I believe that the shooter could have had difficulty in visually determining whether the decedent was a police officer because of low light levels and because of the disability glare from either flashlight that the decedent might have used." The bases for his opinion are photometric measurements and observations at a recreation of the crime scene in February 2015. This expert additionally made two sets of four bracketed-exposure images from both the vantage point of the shooter and of the officer. Referring to an exhibit of two photographs in his report, he stated: "I selected the most realistic exposure from the four exposures for each scene for this exhibit."

An expert witness was retained by the prosecution to review and possibly rebut the analysis and testimony of the defense experts. Subsequent to a pre-trial motion to exclude the defense expert's nighttime photographs, they were withdrawn as evidence. Testimony by the prosecution's expert witness at a pre-trial hearing and as a rebuttal witness at trial concentrated mainly on changes in measured illuminance levels that occurred between the time of the crime in 2010 and both experts' separate inspections in early 2015, as well as the contribution of a 97% full moon that was visible on the night of the crime.

The measured illumination levels and a description of the level of detail that can be seen by an observer under low levels of illumination was an important factor in helping the jury decide whether or not the defendant could identify his victim as a police officer.

Witness Identification, Visibility, Photography

D24 Forensic Engineering Investigation of a Dual Fatality Auto-Pedestrian Collision by an Impaired-Vision Driver

Adam Aleksander, PhD, Aleksander & Associates, PA, PO Box 140558, Boise, ID 83714*

After attending this presentation, attendees will be informed of details of the human visual system that were overlooked by the original law enforcement investigation and that help to explain the technical backdrop to a tragic dual fatality auto-pedestrian collision at a marked crosswalk.

This presentation will impact the forensic science community by discussing trial strategy and the use of witnesses, in addition to the final sentence, consequences for the driver, and implications for driving with impaired vision.

At about 9:30 a.m. on August 19, 2009, an elderly couple, 78 years and 76 years of age, went on their daily walk on the route they followed every day. This included crossing a four-lane suburban road in a residential area. Visibility was unlimited, the weather was clear and sunny, and there was no reason to expect a tragic end to their walk.

At the same time, a 55-year-old male, who was a regional representative for an insurance company and administered many types of accident and litigation claims, left his residence on a seemingly routine drive to his office. A few minutes later, as the couple crossed the street, they were hit in the crosswalk. One died at the scene, the other shortly thereafter at the hospital. The driver pulled over and waited for police. Law enforcement analyzed the location, probable speed, and perception reaction time, in addition to some unexplained behavior at the scene. The driver was charged with the two homicides and driving under the influence; however, he had not drunk any alcohol, but had taken a Benadryl medication, as was prescribed for a chronic illness. Approaching trial, he faced two 15-year terms.

However, the medical record of the driver offered some insight into the collision. He had experienced several brain tumors and surgeries. One of these surgeries inadvertently cut the optic nerve, resulting in total blindness in the right eye and partial loss of vision in the left eye. In fact, he retained only his temporal vision.

The presentation will discuss the details of the visual system, the nasal and temporal visual fields, and why the state of Idaho licensed this individual to drive under these conditions. Perception psychology also comes into play in this instance as humans have remarkable abilities to compensate for visual and sensory deficits.

These considerations were useful in understanding the sequence of events that led to the fatal collision. In fact, the driver saw the couple from a distance, reported that they waved to him to go through the intersection, then lost sight of them until the actual collision, not due to drug impairment, but due to the nature of the visual deficit. The reported wave-through action by one of the decedents had a credible basis and will be discussed. Trial strategy and the use of witnesses will also be discussed as well as the final sentence, consequences for the driver, and implications of driving with impaired vision.

Optic Nerve, Impaired Vision, Crosswalk

D25 A Case Against "Inattentive Driving" as a Cause for Some Nighttime Vehicle Pedestrian Accidents

James B. Hyzer, PhD, Hyzer Research, 1 Parker Place, Ste 330, Janesville, WI 53545-4077*

After attending this presentation, attendees will be aware of a case against "inattentive driving" as a cause for a number of nighttime vehicle pedestrian accidents.

This presentation will impact the forensic science community by explaining that some drivers exercising reasonable care with respect to lookout can and will miss visually perceiving pedestrians in their path under nighttime driving conditions.

A common and obvious cause of numerous roadway accidents is the driver not seeing a pedestrian in time to respond and avoid collision. It is not uncommon for drivers who have hit pedestrians, for example, to report that they "heard the thump but never saw him" or that they "didn't see him until it was too late." Accident reports commonly attribute such claims to "inattentive driving," presumably based on an assumption that a driver who doesn't see a pedestrian who must have been visible couldn't have been paying attention. The job of the expert, then, is to determine whether the signal value of the struck pedestrian was sufficient relative to the driver's visual field to assuredly capture the attention of all alert drivers exercising reasonable care to enable them to respond in time to avoid collision. Through a critical review of published scientific literature, it will be shown that it does not follow that simply because a pedestrian is visible to some drivers, he will necessarily be recognized as a hazard and responded to in time by all drivers exercising reasonable care with respect to lookout.

To correctly express these concepts to a jury, it is important to understand the relevant terminology as it relates to visibility of pedestrians. To *detect* a pedestrian means to discover or determine that something is there; however, a *detected* pedestrian may not necessarily be *recognized* as a pedestrian. To *see* the pedestrian simply means to *perceive* him by the eye or by vision. A pedestrian is *visible* if he is capable of being seen. A pedestrian is *conspicuous* if he attracts or tends to attract the attention of an observer who may not be looking for him. Conversely, a pedestrian is *inconspicuous* if he is not readily noticeable or discoverable by vision. The term *conspicuity*, then, is the capacity of an object, such as a pedestrian, to be readily discovered by vision. Therefore, even though a pedestrian may be in plain sight and visible, he must be sufficiently conspicuous relative to his surroundings to be seen in time by all drivers. At the two extremes, pedestrians that are highly conspicuous should be seen at the greatest possible distances and pedestrians that are highly camouflaged may not be seen or recognized at all.

This presentation offers a case study in which the facts and evidence are inconsistent with the alleged cause of "inattentive driving." It will be shown that in some cases, drivers will miss visually recognizing pedestrians who first become visible at a distance too close to avoid impact because the driver is reasonably paying attention to a location farther ahead in his path and is looking for hazards that he does have time to avoid.

Accident Reconstruction, Visibility, Inattentive Driving

D26 An Engineering Perspective on Case Studies Where Performance Does Not Match Scientific Predictions — The Expansive Nature of Collapsible Soils and Other Engineering Oddities

Michael D. McDowell, MS, 24665 E Ontario Place, Aurora, CO 80016*

After attending this presentation, attendees will be able to: (1) describe how soils issues relate to construction defect claims; (2) describe the challenges in accurately predicting soil behavior; (3) describe potential mistakes made by parties assessing the nature of soil movement; and, (4) present multiple case studies which illustrate engineering oddities and challenges.

This presentation will impact the forensic science community by describing some common challenges when assessing construction defect cases involving soil movement and by improving the understanding of engineering principles which can be applied in the field and laboratory to more accurately evaluate construction claims involving such movements.

Soils-related issues are among the most common allegations described in construction defect claims today. Generally, soils-related allegations include inadequate grading and drainage and questionable soil compaction. The more expensive and troubling allegations generally include foundation modification based on the presence of expansive or collapsible soil. Less common but equally challenging allegations include perched groundwater conditions and corrosive soils. These issues have been documented as being a significant contributing factor to financial demands in construction defect claims. Case review of several hundred construction defect claims has shown that alleged damage related to soils issues constitutes several hundred million dollars in recommended repairs.

Because questionable structural performance may be attributable to a variety of soils-related issues, it is important to adequately assess the composition and behavior of soil in a laboratory. Likewise, it is important to compare one's hypothesis against the performance of the structure (and vice versa). Understanding the nature and predicted performance of soil is generally the first step in a forensic evaluation.

Experience has shown that observational evidence or performance of a structure alone is generally insufficient to provide a scientifically supportable opinion. This is particularly true when formulating opinions on causation or potentially responsible parties. In some cases, settlement of soils may be attributable to design-related issues (e.g., hydro-collapsible or compressible soils) and in other cases, settlement may be attributable to construction-related issues (e.g., inadequately compacted soil). While the term "soil settlement" may be an appropriate diagnosis, it is important to understand the underlying cause of the soil settlement since the observed condition may be attributable to the party who designed the project or the party who constructed it — or potentially both parties.

When assessing soil conditions and resultant structural performance, there are several challenges facing forensic engineers. In the case studies provided, examples will be presented in which the performance of a structure did not match the predictions or opinions offered by the forensic engineer. In a few instances, the performance of a structure was the opposite of the predicted behavior, yet the forensic engineer maintained an unsupportable opinion throughout the course of litigation. The case studies provided will demonstrate that the consistent application of the scientific method will reduce the risk of erroneous opinions.

Structural, Performance, Defects

D27 A Structural Analysis of a Gymnasium Collapse Using the MIDAS Program

Chan-Seong Park, PhD, Division of Forensic Safety, National Forensic Service, 10 Ipchun-ro, Wonju-si, Gangwon-do 220-170, SOUTH KOREA; Jong-Heon Shim, MS, National Forensic Service, 10 Ipchoon-ro, Wonju, SOUTH KOREA; Jin-Pyo Kim, PhD, 1524 Yusungdaero Yusung-gu, Daejeon, SOUTH KOREA; and Nam-Kyu Park, PhD, National Forensic Service, 10 Ipchoonro, Wonju, SOUTH KOREA*

After attending this presentation, attendees will understand the feasibility of using the MIDAS program as a tool for the structural analysis of building collapses.

This presentation will impact the forensic science community by introducing an effective tool for the structural analysis of building collapses.

When analyzing a building collapse, it is imperative to perform a structural analysis; however, in most cases, it is difficult to model the collapsed building structure using general Finite Elements Method (FEM) tools within a restricted time. This study focuses on the effectiveness of the MIDAS program by introducing a case analysis report. As a case report, the structural analysis of the collapsed roof of a gymnasium is presented. The roof of the gymnasium under study was built as a truss structure and collapsed six hours after being built. The roof was supported on one side by hinge structures and on the other side by sliding structures. All the anchor bolts of SS400 carbon steel for the sliding supports fractured with bending. The fractured surfaces of the bolts show dimples without cleavages when examined using a Scanning Electron Microscope (SEM).[1,2] Mechanical properties of the fractured bolts, the hardness, the yield strength, and the ultimate strength were within or slightly above the specified range shown on the material specification when examined using the Advanced Indentation Tester (AIT). The center members of the roof fractured along the wall. The fractured surfaces of center members of the roof showed dimples without cleavages when examined using SEM.

A structure analysis using the MIDAS program was performed by modeling the collapsed roof structure. The MIDAS program serves as a structure wizard with material and section properties, making it possible to easily model the structure.[3,4] The structural analysis revealed that the stress of the center member of the roof exceeded the yielding stress because of sliding supports, which were the main cause of the collapse.

Structural Analysis, Building Collapse, MIDAS Program

D28 Forces Transmission to the Skull in a Case of Mandibular Impact

Lucile Tuchtan, MD, 63 Chemin Des Aurengues, Marseille 13013, FRANCE; Marie-Dominique Piercecchi-Marti, PhD, 264 Rue Saint Pierre, Marseille 13005, FRANCE; Christophe Bartoli, MD, 264 Rue Saint Pierre, Marseille, FRANCE; Pascal Adalian, Laboratoire ADES, Marseille, FRANCE; Georges Leonetti, PhD, 264 Rue Saint Pierre, Marseille, FRANCE; and Lionel Thollon, 264 R St Pierre, Marseille, FRANCE*

After attending this presentation, attendees will better understand direct mandible impact, the level of energy required to create a mandible fracture, and the energy dispersion to the skull and to the brain.

This presentation will impact the forensic science community by providing a better understanding of the force transfer mechanisms into and from the mandible.

Background: Forensic investigations have been reported regarding the loss of consciousness and cardiac arrests resulting from direct mandible impact; however, the mechanisms by which the forces are transferred to the skull through direct mandible impact remain unclear.[1] A study was conducted regarding direct mandible impact on the level of energy required to create a mandible fracture and on the energy dispersion phenomenon to the skull and to the brain.

Materials and Methods: This study combines an experimental and numerical approach. Mandible strike was studied using experimental trials performed on postmortem human subjects. A finite element model of the head and face of a male was also developed based on tomodensitometry scans. The model was validated with literature data and experimental trials. A parametric study was then performed to study the effect of diverse variables such as the dentition integrity, cortical bone thickness, etc.

Results: The forces measured on the reference model were 3,000N on the chin, 1,800N at the condyles, and 970N in the occiput. Of all the results, a decrease of approximately one-third of the efforts from the chin to the base of the skull and a lower half of the still forces at the occiput was observed, except in the edentulous and for the lateral and frontal impact where the force is transmitted directly to the skull base area.

In this study, the skull model was validated to demonstrate the energy transmission to the skull, but the focus was the von Mises stress distribution of the cerebral pressure areas. The von Mises stress was distributed with an anterior-to-posterior orientation through the temporal lobe and ended at the brainstem level. Viano et al. found that a hook strike increases the stress in the temporal region and at the midbrain level.[2] Belingardi et al. developed a Finite Element Method (FEM) of the head based on the experimental trials performed by Nahum et al. and found increased cerebral pressure with significant stress in the coronal section of the brainstem, which confirms its pivotal role in movement of the brain.[3,4]

Thus, it can be supposed that during an uppercut, part of the impact energy reaches the brainstem, which is obviously supported by the levels of stress found at the condyles during the simulations and the fractures observed at the temporomandibular joint in both experiments. This result is interesting from a forensic point of view because the pressures observed in the brainstem could lead to a vagus nucleus stimulation, which may be involved in cardiac arrest via the cardio-inhibitory reflex.

Conclusion: A 3D model of the mandible and face bones was created for this study to better understand the force transfer mechanisms into and from the mandible. The parameters of the model may be modified to suit the individual characteristics for forensic investigations and legal matters.

D29 Forensic Engineering Examination of Stucco on a Concrete Masonry Unit (CMU) Wall, Paint Layer Evidence, and Crack Propagation

Adam Aleksander, PhD, Aleksander & Associates, PA, PO Box 140558, Boise, ID 83714*

After attending this presentation, attendees will be informed of a basic method of determining the ordering and timing of paint layer application on a stucco surface applied to a CMU wall structure.

This presentation will impact the forensic science community by explaining how this method of examining the time-related ordering of paint deposition was critical to understanding the sequence of paint material application and subsequent fracture propagation through the structure.

Two basic methods have been used for centuries in the scientific and engineering examination of materials — surface examination and cross-section inspection.

Cross sections are commonly used in many disciplines, including engineering, material science, and medicine. For example, sections through welds or fractures are a primary means of metallurgical analysis. Similarly, Computed Axial Tomography (CAT) scans and Magnetic Resonance Imaging (MRI) techniques are now everyday terms and are, in effect, sophisticated cross-section methods to analyze the human body.

In this case, sections of stucco were removed, sectioned, polished, and magnified. A clear sequence of events was developed based on the physical evidence, namely identification of individual paint layers, the sequence of application, and the intrusion of paint into pre-existing fractures.

In spite of disproportionately vigorous and impassioned objections and motions *in limine* from opposing attorneys, this cross-section method was in fact grudgingly admitted at trial by the judge, and is described in this presentation, along with the illustrative exhibits and related graphics. Since the opposing attorney stridently objected to this method as being novel and unpublished, it is being presented through this presentation.

The underlying case concerned a substantial CMU structure that was originally built in September of 2001, and coated with a white primer paint approximately 30 days later. Subsequently, in the following months a brown pigment paint layer was applied. In the following years, an additional coat of a similar brown pigment paint was applied. In 2012, municipal road improvement construction along the wall was alleged to have created a network of fractures and cracks in the CMU wall. Furthermore, numerous learned reports were submitted by various experts alleging that the fractures could be explained by engineering formulations and other arguments. None of the reports effectively refuted the physical evidence that the fractures were in fact evident well before the date of the municipal construction, time stamped by the order of paint application; this evidence will be presented.

NACE International (formerly National Association of Corrosion Engineers) identifies tools and methods to examine paint thickness, but these methods are not applicable to this type of investigation. The method described in this investigation may be useful in similar future investigations.

Briefly described, the method was to adhere a 3”x3”x$^{1}/_{8}$” (75mm x 3mm) Fiberglass Reinforced Plastic (FRP) laminate with a generous layer of epoxy over a fracture line of interest. The FRP laminate was taped in place and allowed to cure for 24 hours. A diamond blade on a portable grinder was used to cut a 4” coupon from the stucco wall, removing the FRP laminate and the attached stucco layer (this also exposed the underlying prior fracture in the CMU). The FRP laminate preserved the geometric relationship in the stucco section and preserved the fracture features. The FRP surface was marked, photographed, then the entire sample was sectioned on a masonry diamond blade wet cutter. The sections were $^{3}/_{4}$” (20mm) thick, resulting in four sectioned samples per location.

Each cut section was then polished on a wet diamond lapidary surface. The resulting finished samples were then photographed and measured using both optical and digital microscopes. The resulting inspection and analysis clearly revealed the individual paint layers, allowed dimensional measurements, and illustrated the intrusion of paint into the pre-existing fractures long before the construction began near the CMU wall in question. This data will be presented.

CMU, Stucco, Paint Layer

D30 Fuel Gas Odorization: History, Requirements, Application, and Challenges for Natural Gas and Propane

Tim G. Dunn, MS, Dunn Laboratories, Inc, 230 Spring Ridge Trace, Roswell, GA 30076*

After attending this presentation, attendees will gain insight into the history of fuel gas odorization, present applications for odorizing natural gas and propane, and the challenges faced for the odorant to provide a means of warning.

This presentation will impact the forensic science community by providing an understanding of the issues pertaining to gas odorization.

For many forensic engineers, the first question following a fuel gas explosion or fire is whether victims or witnesses noticed a gas odor, and if not, why not? The practice of adding a malodorant to a fuel gas goes back to the 1880s, when ethyl mercaptan was used to odorize water gas — hydrogen/carbon monoxide. For many years, coal gas, which contained a substantial level of carbon monoxide, obviously making it very toxic fuel gas, was used in both Europe and the United States. From the 1950s to the mid-1960s, new transmission pipelines brought natural gas to various parts of the country, bringing with it more focus on odorization practices.

There were several studies conducted by the United States Bureau of Mines (BOM) from 1919 to 1931 that addressed the topic of warning agents for fuel gases. In the 1931 BOM study, other means of warning were considered, such as the use of irritants (eye, nasal) and sternutators (sneezing agents).[1] Many of the warning agents were limited by the fact that they were unsuitable due to toxicity or corrosivity. This study reached the conclusion that ethyl mercaptan was the most effective product for causing complaints of leaks; crotonaldehyde, an irritant, was determined to be the next best candidate. The necessity for a warning agent in fuel gases came to the forefront following the natural gas explosion at the New London/Texas High School, which occurred on March 18, 1937: 239 persons lost their lives from the results of a leak of unodorized gas piped into the building from a nearby oil field. The day after this accident, the State of Texas proposed the first law requiring that fuel gases be odorized. The requirement for odorizing propane came a short time later with the National Bureau of Fire Underwriters (NBFU) (the predecessor to the National Fire Protection Association (NFPA)) pamphlet 58.

The Natural Gas Pipeline Safety Act of 1968 delegated responsibility for regulation and monitoring of pipeline transport of gas to the Secretary of Transportation. The Office of Pipeline Safety was formed in 1968. In the Code of Federal Regulations, 49CFR Part 192.65, Odorization of Natural Gas specifies the following: "(a) A combustible gas in a distribution line must contain a natural odorant or be odorized so that at a concentration in air of one-fifth of the lower explosive limit, the gas is readily detectable by a person with a normal sense of smell." For propane, similar requirements were found in the Liquefied Petroleum (LP) Gas Code, National Fire Protection Association (NFPA) pamphlet 58: "All LP-Gases shall be odorized prior to delivery to a bulk plant by the addition of a warning agent of such character that the gases are detectable, by a distinct odor, to a concentration in air of not over one-fifth the lower limit of flammability." The challenge presented by these situations is to apply engineering principles to meet these performance standards!

This presentation will discuss the means by which natural gas and propane is odorized, describe the prominent odorants used today, and the challenges encountered for an odorant-based warning system. With propane, the presentation will discuss the 1977 testing conducted in the Bartlesville study, additional testing by the Institute of Gas Technology, now Gas Technology Institute (GTI), and testing performed with released fuel gas in Round Lake, MN.[2]

Due to the properties of fuel gases and the results of the testing, the conclusion reached is that electronic flammable gas detectors offer an added level of safety to the gas consumer.

Odorization, Fuel Gas, Warning Agent

D31 Redesign of a StepMeter for Direct *In Vivo* Measurement of Barefoot Skin Friction

Marcus P. Besser, PhD, Pennsylvania State University Abington College, 1600 Woodland Road, Abington, PA 19001-3900; and Mark I. Marpet, PhD, PE, 14 Cowie Road, Chester, NJ 07930-9715*

After attending this presentation, attendees will understand some of the issues in barefoot tribometric slip-resistance testing, specifically assessment of barefoot slip resistance, and how current research is being conducted to address these issues and improve the biofidelity of these measurements.

This presentation will impact the forensic science community by allowing the collection of a cohort of data on barefoot subjects to characterize the subject-to-subject variation in barefoot pedestrian slip resistance on different surfaces.
